DEDICATED TO THE MEMORY OF PROFESSOR IRVING LYNN

1. INTRODUCTION

The purpose of this paper is twofold: first we show that all the systems discussed in Adler and van Moerbeke [2] (paper I) in connection with Kac-Moody Lie algebras can be linearized according to a general scheme common to all of them reminiscent of Mumford and van Moerbeke's treatment of the Toda lattice [16]. The methods reflect the decomposition of the Lie algebra as explained in I and therefore are divided into two different sections dealing on the one hand with Toda-type flows and on the other hand with flows of spinning top type (Sections 2 and 3).

The second part of the paper adresses the following problem: each Lie algebra representation leads to a different curve and therefore a different Jacobi variety; therefore one might expect the linearization to depend on the representation; i.e. the same flow would lead to essentially different solution by quadratures, depending on the representation. We show this is not the case, because the Jacobi varieties corresponding to higher-order representations all contain one or several copies of the Jacobi variety going with the fundamental representation. To show this, use is made of the theory of correspondences: a correspondence is established between the fundamental curve and the curves corresponding to higher-dimensional representations; the latter curves are Galois extensions of the fundamental curve. Such a correspondence induces a homomorphism between the associated Jacobi varieties, which is shown to be different from zero and injective; the first statement follows from an inequality of Castelnuovo and the second from the irreducibility of the Jacobians for Toda-like

curves. In an appendix we sketch the main concepts and theorems of the theory of correspondences in a style reminiscent of the classic Italian geometers.

2. Linearization of the Toda-Type Flows

In I, Sect. 4, we discussed special orbits of the classical Lie groups of minimal dimension. For $sl(n)$, these orbits gave rise to the classical Toda systems. However, for the other groups, discussed in I, Section 4, they give rise to generalizations of this system; their linearization will be dealt with in this section. We first state the main theorems which emphasize the analogies and the differences between these cases. It is interesting to point out that the distinction between the Lie algebras reflect themselves at the level of the curves and/or the way the isospectral set is embedded in the Jacobi variety.

We first sketch the proof of the theorem for $sl(n)$ (cf. Moerbeke [15]), then we linearize the problem in detail for $so(n, n + 1)$ and sketch the proofs for the other groups; the case $G_2$ is covered by $so(3, 4)$ and some additional structure. As compared to $sl(n)$ the methods involve particular attention to the special symmetries and degeneracies inherent in the description of the Lie algebras; they reflect themselves in Prym subvarieties on which the flows evolve.

Consider a matrix $A_h$ in the orbit corresponding to any of the Toda matrices (I, Sect. 4) associated to the classical groups and $G_2$, specifically (4.24), (4.25), (4.26), (4.27), (4.28). Remember that to each matrix $A_h$ is associated the curve $X$ given by

$$Q(z, h) = \det(A_h - zI) = 0.$$  

For every group above, define the isospectral set $\mathcal{A}(X)$, defined by a given curve $X$, and the functions $z$ and $h$ on it: $\mathcal{A}(X) = \{A_h \mid \det(A_h - zI) = Q(z, h)\}$ modulo a discrete group action. This action takes on the following form for

1. $sl(2n)$: conjugation by diagonal matrices with entries $\pm 1$.

2. $so(n, n + 1)$: (i) the conjugation by diagonal matrices of the form $\text{diag}(a_1, b)$ where $a = \text{diag}(\pm 1, \pm 1, \ldots, \pm 1)$ of size $n$ and $b$ is the same diagonal matrix read right to left
   (ii) interchanging $a_1$ and $a_{n+1}$ and also $-b_1$ and $b_1$ simultaneously.

3. $so(n, n)$: (i) the conjugation by diagonal matrices of the form $\text{diag}(a, b)$ where $a = \text{diag}(\pm 1, \ldots, \pm 1)$ of size $n$ and $b$ is the same diagonal matrix read right to left.
   (ii) interchanging $a_1$ and $-a_{n+1}$ and also $-b_1$ and $b_1$ simultaneously.
   (iii) interchanging $a_n$ and $a_{n-1}$ and also $-b_n$ and $b_n$.

For analogy we have picked the even-dimensional case which is not different from the odd case.
(4) $sp(n)$: conjugation by the same matrices as in (3i)

(5) $G_2$: conjugation by the same matrices as in (3i) with $n = 3$ and $a$ as in the above, but in addition restricted to be of the form $(d_1, d_2, d_3 d_4)$.

**Theorem 1.** (a) Any matrix of the form $A_h$ with all $a_k \neq 0$ leads to a hyperelliptic curve $X$ (with hyperelliptic involution $\tau$) of genus $g = 2n - 1$ having two distinguished non-constant meromorphic functions $h$ and $z$ and distinguished points $P, Q = P^\tau, R, S = R^\tau$ such that $(z) = -P - Q + R + S$.

Except for $sl(n)$, it has the extra-involution $\sigma$ defined by

$$\sigma: (z, h) \rightarrow (-z, h).$$

The set of matrices $\mathcal{A}(X)$ maps one-to-one onto a set (containing a Zariski open set) in the variety $Y$ defined below; let $J$ be the natural embedding of $Y$ in $Jac(X)$.

(b) Every linear flow on $Y$

$$\int_{\mathcal{D}(t)} \mathcal{D}(0) \omega_k = a_k J, \quad a_k = 0 \text{ for } k \text{ even (except for } sl(2n)),$$

$^a$ refers to equivalence in terms of Abelian sums.

$^a \omega_j = z^i y^j - 1 ds$, $y$ hyperelliptic irrationality. For a divisor $\mathcal{D} = \sum_{i} \mu_i$, $\omega_j(\mathcal{D}) = \sum_{i} \int_{\mathcal{D}} \omega_j = \int_{\mathcal{D}} \omega_j$ for some appropriate choice of origin.
is associated with a polynomial $T(z)$ of degree $\leq g$, which except for the case of $\mathfrak{sl}(n)$ is odd; $T(z)$ is chosen such that

$$a_k = \text{Res}_z(\omega_k T(z)).$$

This flow translates into a system of differential equations given by

$$\dot{A} = [A, P_k(T(A))], \quad P_k(T(A)) = T(A)^+$$

(strictly “upper triangular” part of $T(A)$ in the sense of Kac–Moody (I, Sect. 3)).

**Remark 1.** The algebras differ from $\mathfrak{sl}(2n)$ by the presence of the involution $\sigma$. The algebra $\mathfrak{so}(n, n)$ differs from the other algebras from the point of view of the function $h$, which imposes different conditions on the curve. The algebras $\mathfrak{sl}(2n)$, $\mathfrak{so}(n, n + 1)$, and $\mathfrak{sp}(n)$ all give rise to the same curve via the relation between $h$ and $z$. In addition, the cases $\mathfrak{so}(n, n + 1)$ and $\mathfrak{sp}(n)$ give rise to the Prym variety $\sigma$ on $\text{Jac}(X)$. However, at the level of $Y$ (divisors) things are different, as is seen from the table.

**Remark 2.** Except for $\mathfrak{sl}(2n)$ and $\mathfrak{sp}(n)$, the various cases present degeneracies and seemingly non-uniqueness of the map $\mathcal{A}(x) \rightarrow Y$ due to $O(\mathcal{D}) = g + 1 > g$. However, the symmetries inherent in the matrices eliminate the non-uniqueness. The more complicated “boundary conditions” suggest the use of a Wronskian-type function.

**Sketch of the proof for $\mathfrak{sl}(N)$.** The curve $X$ of genus $g$, defined by $Q(z, h) = \det (A_h - zI) = 0$ has the above properties, where $h$ and $z$ are regarded as meromorphic functions on $X$. The elements of the eigenvector $f = (f_0, f_1, \ldots, f_{N-I})^t$ defined by $A_h f = z f$ and normalized at $f_0 = 1$ are considered to be meromorphic functions on the curve; they are defined by

$$f_k = \frac{\Delta_{N,k}}{\Delta_{NN}} h,$$

where $\Delta_{ij}$ stands for the minor of $A_h - zI$ corresponding to the $i, j$th entry; one further defines $f_{k+jN} = h^j f_k, j \in \mathbb{Z}$; one verifies that

$$(f_k) \geq -\mathcal{D} - kP + kQ$$

with equality at $P$ and $Q$ and $\mathcal{D}$ minimal; moreover $\mathcal{D}$ has order $g$ and dim $\mathcal{L}(\mathcal{D} + kP - (k + 1)Q) = 0, k \in \mathcal{L}$. Given a divisor of order $g$ satisfying the latter property, one constructs uniquely a set of functions $f_k$ satisfying (1) and these define the matrix $A_h$ above uniquely via the relation

$$zf = A_h f.$$
Consider the flow

$$A' = [A, P_{x}(T(A))] = [A, B],$$

(2)

where $T(z)$ is a polynomial of degree $\leq g$. As an ordinary differential equation for the entries $a_k$ and $b_k$, this Lipchitzian flow exists for $0 \leq t < \epsilon$. For $\epsilon$ small enough, the set of divisors $\{D(t) \mid 0 \leq t < \epsilon\}$ projects into a compact set in $\mathbb{C}^g$, on which $|h|$ is bounded by $M$. Let $U(t)$ be the finite matrix, analytic in $h$ and $t$, defined by\(^5\)

$$U(t) = UB, \quad U(0) = I, \quad |h| \leq M, \quad 0 \leq t \leq \epsilon' < \epsilon.$$

Hence

$$U(t) = I + tB(0) + O(t^2), \quad |h| \leq M,$$

where, by considerations of $I$, Section 4, the infinite-dimensional representation of $\hat{B}$ is a strictly upper triangular matrix; hence $\hat{B}$ is analytic in $h$ and $t$, never containing $h^{-1}$. Since $U(t)$ makes the eigenvectors move, we have\(^5\) that $(I + t\hat{B}) f(0)$ and $f(t)$ are proportional vectors; so let

$$(I + t\hat{B}) f(0) = (1 + tg) f(t),$$

(3)

where, by equating the 0th entry of both vectors, we compute that

$$1 + tg = 1 + t(\hat{B} f(0))_0$$

$$= 1 + t(B f(0))_0 + O(t^2);$$

$$= 1 + t \sum_{i \geq 1} B_{ii} f_i(0) + t \sum_{i \geq 1} O(t) f_i(0)$$

(4)

$$= 1 + tg(0) + \sum_{i \geq 1} O(t^2) f_i(0)$$

with $O(t^2)$ analytic in $h$. Since $D$ is the minimal set of poles on $X_0 = X \setminus P \cup Q$ of the left-hand vector in (3) and since the new divisor $D(t)$ of $f(t)$ (after flowing by (2)) is generally distinct from $D$, the divisor of poles of $1 + tg$ must be $D_0$, at least within $X_0$. Since the minimal divisor of poles of $f(t)$ is $D(t)$ and since the left generally does not have poles at $D(t)$, we conclude that

$$(1 + tg)_0 = D(t) - D$$

and from the last equality in (4),

$$(1 + tg(0))_0 = D'(t) - D$$

\(^5\) $f(0) = f|_{t=0}$, $B(0) = B|_{t=0}$.
for some divisor $D'(t)$ near $D$. By manipulating power series and using the fact that the above functions differ by $O(t^2)$, it is easy to show that pointwise

$$D(t) - D'(t) = O(t^2).$$

(5)

Since $g(0) = \sum_{i>1} B_{0i}(0) f_i(0)$, which is a finite sum extending up to $K$, for instance,

$$\left(\frac{1}{t} + g(0)\right) = -KP - D + D'(t) + \sum_{i} P_i(t),$$

where the points $P_i(t)$ are near $P$ for $t$ small. Using Abel's theorem, for every holomorphic differential

$$\int_{\mathcal{D}'} \omega = -\sum_{i} \int_{P_i(t)} \omega,$$

which by a lemma in Mumford and Moerbeke [16, Sect. 4.2]

$$= -t \text{Res}_{P}(\omega g(0)) + O(t^2)$$

$$= -t \text{Res}_{P}(\omega T) + O(t^2);$$

the latter equality holds, because $(P_{X}(T(A)) f)_{0} = \sum_{i>0} B_{0i}(0) f_i$ contains the polar part (at $P$) of $(T(A) f)_{0} = T(z)$. Therefore,

$$\frac{d}{dt} \int_{\mathcal{D}'} \omega \bigg|_{t=0} = -\text{Res}_{P}(\omega T).$$

Proof of Theorem 1 for so(n, n + 1). Let $\sigma$, applied to matrices, be the operation of taking the transpose about the minor diagonal. $X$ shall be the curve defined by

$$Q(z, h) = \det(A_h - zI) = 0.$$

Then

$$Q(-z, h) = \det(A_h + zI) = \det(A_h + zI)^n = (-1)^{2n+1} \det(A_h - zI) = -Q(z, h),$$

i.e., $Q(z, h)$ is odd in $z$ and therefore $Q(z, h)$ has a $z$-factor. Simple inspection of the matrix shows that

$$Q(z, h) = (-1)^{n+1} \left[ 2A(h + h^{-1}) + (-1)^{n} q(z^2) \right],$$

(6)

where $g$ is a monic polynomial of degree $n$ and

$$A = a_1 \prod_{2}^{n} a_i^2 a_{n+1}.$$
This hyperelliptic curve $X$ of genus $g = 2n - 1$ (odd) clearly has the two involutions

$$\tau: (z, h) \rightarrow (z, h^{-1})(\text{hyperelliptic}) \quad \text{and} \quad \sigma: (z, h) \rightarrow (-z, h).$$

Moreover, by (6)

$$(h) = -2nP + 2nQ \quad \text{and} \quad (z) = -P - Q + \text{two zeros}.$$

The eigenvector $f = (f_{-n}, f_{-n+1}, \ldots, f_{-1}, f_0, f_1, \ldots, f_{n-1}, f_n)^{\omega}$ of $A_h$ with $f_0 = 1$ can be extended as usual to an infinite vector using the relation

$$h^j f_k = f_{k+j(2n+1)}, \quad j \in \mathbb{Z}.$$ 

The meromorphic functions

$$f_k = \frac{\Delta_{n+1,n+1+k}}{\Delta_{n+1,n+1}} = \frac{\Delta_{n+1+k,n+1+k}}{\Delta_{n+1+k,n+1}}$$

have the properties

$$(f_k) \geq -\mathcal{D} - kP + kQ, \quad -n \leq k \leq n, \quad \text{with equality at } P \text{ and } Q, \quad (8)$$

where $\mathcal{D}$, a positive divisor of order $g + 1 = 2n$, satisfies $\mathcal{D}^\tau = \mathcal{D}^\sigma$ and is minimal with regard to (8). The proof breaks up into several lemmas.

**Lemma 1.** The order of the pole of $f_k$ at $P$ equals the order of zero at $Q$.

First we observe that$^6$

$$(\Delta_{ij})_\infty = -2nP - 2nQ. \quad (9)$$

This is so, because $\Delta_{ij}$ is a monic polynomial of degree $2n$ in $z$, except for $j = 1$ or $2n + 1$ where it contains an extra term in $(h + h^{-1})$ with coefficient $A$, instead of $2A$. Second, let

$$(\Delta_{n+1,n+1+k})_\infty = -\alpha P - \beta Q, \quad \alpha, \beta \in \mathbb{Z},$$

Then on the one hand,$^7$ since $(\Delta_{ij})^\tau = \Delta_{ji}$ and $P^\tau = Q$,

$$(\Delta_{n+k+1,n+1})_\infty = -\beta P - \alpha Q, \quad (10)$$

$^6$ $(\cdot)_\infty = (\cdot)_{PQ}$.

$^7$ $\Delta(z, h)^\tau = \Delta(z, h^{-1})$. 
and on the other hand, because of (7), (9) and (10)

\[ (\Delta_{n+k+1,n+1})_\infty = (\Delta_{n+1,n+k+1})_\infty + (\Delta_{n+1,n+1})_\infty - (\Delta_{n+1,n+k+1})_\infty \]
\[ = -(4\alpha - n\alpha)P - (4\alpha - n\beta)Q. \]

Comparing (10) and (11), \(\alpha + \beta = 4n\) holds and therefore, since

\[ (f_k)_\infty = (\Delta_{n+1,n+1+k})_\infty - (\Delta_{n+1,n+1})_\infty \]
\[ = -(\alpha - 2n)P + (-\beta + 2n)Q, \]

the order of the pole of \(f_k\) at \(P\) equals the order of zero at \(Q\).

**Lemma 2.** Statement (8) holds.

To begin with, observe that

\[ (f_k)_\infty = -(f_{-k})_\infty, \]

as follows from

\[ (f_k)_\infty = \left(\frac{\Delta_{n+1,n+k+1}}{\Delta_{n+1,n+1}}\right)_\infty = \left(\frac{\Delta_{n+1,n+k+1}}{\Delta_{n+1,n+1}}\right) = \frac{\Delta_{n+1,n+1-k}}{\Delta_{n+1,n+1}} = f_{-k}. \]

From the relation (12) and (see I (4.26))

\[ z = zf_0 = a_n f_{-1} - a_n f_1 \]

either \(f_1\) or \(f_{-1}\) has a simple pole at \(P\). First, assume it to be \(f_1\); then from the relation

\[ zf_1 = -a_n f_0 - b_n f_1 - a_{n-1} f_2 \]

it follows that \(f_2\) has a double pole at \(P\); so, in general, using a similar argument,

\[ (f_k)_\infty = -kP + kQ, \quad -n + 1 \leq k \leq n - 1. \]

From the relation

\[ zf_{n-1} = -a_2 f_{n-2} - b_2 f_{n-1} - a_1 f_n + a_n f_{n+1} \]

it follows that

\[ (a_1 f_n - a_{n+1} f_{n+1})_P = -nP. \]

Next we show that \(f_n\) and \(f_{n+1}\) both have a pole of order \(n\) at \(P\). Indeed, assume

\[ (f_n)_P = -\beta P, \]
hence, using (12) in the second equality

\[(f_{n+1})_P = (hf_{-n})_P = -(2n - \beta)P;\]

If \(\beta \neq n\), then of the two numbers \(\beta\) and \(2n - \beta\), one would be larger than and the other smaller than \(n\), contradicting (14). There remains the possibility that \(f_{-1}\) has a simple pole at \(P\); then using the linear relations, as before,

\[(f_k)_P = -kP - kQ, \quad -n + 1 \leq k \leq n - 1,\]

and, according to the relation

\[zf_{-n+1} = -a_{n+1}f_{-n} + a_1f_{-n} + b_2f_{-n+1} + a_2f_{-n+2}\]

we have that

\[(-a_{n+1}f_{-n} + a_1f_{-n})_P = -nP. \quad (15)\]

Let

\[(f_{-n})_P = -\beta P;\]

then, again using (12),

\[(f_{-n-1})_P = (h\bar{f}_n)_P = (\beta + 2n)P.\]

Either \(\beta \geq n\) or \(\beta < n\); in the first case, in view of (14), \(\beta + 2n = -\beta\), i.e., \(\beta = -n\), which contradicts \(\beta > n\). In the second case, \(\beta + 2n = -n\), i.e., \(\beta = -3n\). Then, the relation

\[zf_{-n} = a_{n+1}f_{-n-2} + b_1f_{-n} + a_1f_{-n+1}\]

and the fact that \(f_{-n-2} = h^{-1}f_{n-1}\) leads to the contradiction

\[-(zn + 1)P = (f_{-n-2})_P = (h^{-1}f_{n-1})_P = (2n + (n - 1))P.\]

This establishes (8) at the points \(P\) and \(Q\). Let \(D\) be the minimal positive divisor satisfying (8); it has finite order, because every function \(f_i(k \in \mathbb{Z})\) is obtained from the finite list \(f_j (\neg n \leq j \leq n)\) by multiplication with an appropriate power of \(h\). Moreover, since \(f_{-1} = f_k^*\), we have \(D^* = D\); the fact that \(O(D) = 2n\) will be established later.

Define

\[Y_0 = \{D | D \geq 0, D^* = D^0, O(D) \leq 2n\} \subseteq \bigcup_{i=1}^{2n} S^i(X)\]

and

\[A(X) = \{A_h\} \text{ of type above; det}(A_h - zI) = Q(z, h)\]

mod the discrete group action. So far we know that \(A_h\) maps into a divisor \(D\)
where the functions are uniquely determined by the relations

\[
\begin{align*}
(\hat{g}_2)_{\infty} &= -P + Q, & (\hat{g}_2 - z)_P &\geq P, & (\hat{g}_2)_0 &\geq -D \\
(\hat{h}_2)_{\infty} &= Q, & (\hat{h}_2 - 1)_P &\geq P, & (\hat{h}_2)_0 &\geq -D
\end{align*}
\]

and similarly for \( \hat{g}_{-1} \) and \( \hat{h}_{-1} \) with \( P \) and \( Q \) interchanged. Equation (25) will now be used to determine \( b_1 \) and \( \alpha \). As before, we make the generic assumption that \( b_1 \) and \( b_1'\) are not in \( D \). Therefore from (25)

\[
\begin{align*}
\alpha g_{-1}(-h_1) + \alpha^{-1}g_2(-h_1) &= 0, \\
\alpha g_{-1}(-b_1') + \alpha^{-1}g_2(-b_1') &= 0,
\end{align*}
\]

which implies that

\[
(g_{-1}g_2^* - g_{-1}^*g_2)(-b_1) = (g_{-1}g_2^* - g_{-1}^*g_2)(-b_1') = 0.
\]

Hence,

\[
W(z) \equiv (\hat{g}_{-1} + zh_{-1})(\hat{g}_2^* + zh_2^*) - (\hat{g}_{-1}^* + zh_{-1}^*)(\hat{g}_2 + zh_2)
\]

vanishes at \(-b_1\) and \(-b_1'\). From a similar argument where \( f_0 \) is normalized at 1, instead of \( f_1 \) (thus the roles of \( f_0 \) and \( f_1 \) and \( b_1 \) and \(-b_1\) are interchanged), we have that \( W(z) \) also vanishes at \( b_1 \) and \( b_1' \). Moreover from (28),

\[
(W(z)) \geq D - D^* + b_1 + b_1' + b_1^* + b_1'^* - 2P - 2Q + \text{all } 4n \text{ branch points}
\]

and hence equality; then we conclude \( o(D) = 2n \) and the zeros of \( W(z) \) are precisely the zeros specified. Therefore \( \alpha \) is determined uniquely by (29) and so is \( f_0, g_{-1}, g_2 \). Using the next relation in the set of relations \( A_h f = zf \), one shows that \( f_2 \) is uniquely determined up to a constant factor by an argument similar to Lemma 4 and in the fashion for \( f_k \) \((-n + 2 \leq k \leq n + 1)\). First by the periodicity relations \( hf_k = f_{k+2n} \) for \(-(n - 2) \leq k \leq (n - 1)\), are determined. Using the \( n \)th and \((n + 1)\)th relation in \( A_h f = zf \), and by an argument precisely the same as that used to determine \( f_n, f_{n+1} \) in Lemma 4, we see that indeed \( f_n, f_{n+1} \) are uniquely determined (modulo the group action). We have thus determined the \( f_i \) uniquely up to the map \( f_i \to c_i f_i \); however, the symmetry of the \( A_h \) shows that \( c_i^3 = c_i \) for all \( i, j \); hence the matrix \( A_h \) is indeed uniquely determined modulo the group action. The linearization argument proceeds exactly as for \( sl(n) \) with the modifications made for \( so(n n+1) \).

**Proof of Theorem 1 for \( sp(n) \).** The curve \( X \) is the same as the one for \( sl(2n) \) with the additional \( \sigma \) involution. The example is of course a subcase of \( sl(2n) \);
and the fact that $\Delta_{n+1,n+1}$ is fixed under $\tau$ and $\sigma$, the zeros of $\Delta_{n+1,n+1}$ have the structure

$$(\Delta_{n+1,n+1}) = \sum_{1}^{n} \mu_{i} + \sum_{1}^{n} \mu_{i}^{\tau} + \sum_{1}^{n} \mu_{i}^{\sigma} + \sum_{1}^{n} \mu_{i}^{\sigma \tau} - 2n(P + Q).$$

We show that, possibly after relabeling,

$$D = \sum_{1}^{s} \mu_{i}^{\sigma} + \sum_{1}^{s} \mu_{i}^{\tau} \quad (s \leq n).$$

First we define the divisors $\sum_{i=1}^{4n} \alpha_{i}$, $\sum_{i=1}^{2n} \xi_{i}$, by

$$(\Delta_{n+1,n+2}) = \sum_{1}^{4n} \alpha_{i} - 2nP - 2nQ,$$

$$(\Delta_{n+2,n+2}) = \sum_{1}^{2n} \xi_{i} + \sum_{1}^{2n} \xi_{i}^{\tau} - 2nP - 2nQ.$$

The latter is permitted because of the generic assumption

$$(G^{\tau}) \quad \Delta_{n+2,n+3} \quad \text{and} \quad q(z^{2})^{2} - 4A^{2} \quad \text{do not vanish simultaneously. Using} \quad \text{the fact that}$$

$$f_{1} = \frac{\Delta_{n+1,n+2}}{\Delta_{n+1,n+1}} = \frac{\Delta_{n+2,n+2}}{\Delta_{n+2,n+1}},$$

and the relation $\Delta_{n+1,n+2} = \Delta_{n+2,n+1}$, we have that

$$\sum_{1}^{4n} \alpha_{i} - \sum_{1}^{n} \mu_{i} - \sum_{1}^{n} \mu_{i}^{\tau} - \sum_{1}^{n} \mu_{i}^{\sigma} - \sum_{1}^{n} \mu_{i}^{\sigma \tau} = \sum_{1}^{2n} \xi_{i} + \sum_{1}^{2n} \xi_{i}^{\tau} - \sum_{1}^{4n} \alpha_{i}^{\tau}$$

$$= (f_{1})_{0} = D' - D,$$  \hspace{1cm} (17)

where the points of the positive divisor $D'$ are distinct from those of $D$. Cancellation must take place on the left-hand side, because otherwise, say, $\mu_{1}$ would appear among the $\alpha_{i}^{\tau}$'s and $\mu_{1}^{\tau}$ would cancel with one of the $\alpha_{i}$'s. So by possibly relabeling, let $\mu_{1} = \alpha_{1}$; then by $(G_{3})$, $\mu_{1} \notin D$ and $\mu_{1}^{\sigma \tau} \notin D^{\sigma \tau} = D$. Hence $\mu_{1}^{\sigma}$ must also cancel on the left-hand side; let $\mu_{1}^{\sigma} = \alpha_{3}$. Therefore, among the points $\mu_{1}, \mu_{1}^{\tau}, \mu_{1}^{\sigma}, \mu_{1}^{\sigma \tau}$ only $\mu_{1}^{\tau} + \mu_{1}^{\sigma} = \alpha_{1}^{\tau} + \alpha_{3}^{\tau}$ could appear in $D$. Then, after canceling this expression on the left- and right-hand sides of the first equality (17) one gets

$$\sum_{1}^{4n} \alpha_{i} - \sum_{1}^{n} \mu_{i} - \sum_{1}^{n} \mu_{i}^{\tau} - \sum_{1}^{n} \mu_{i}^{\sigma} - \sum_{1}^{n} \mu_{i}^{\sigma \tau} = \sum_{1}^{2n} \xi_{i} + \sum_{1}^{2n} \xi_{i}^{\tau} - \sum_{1}^{4n} \alpha_{i}^{\tau};$$

then also, on the right-hand side, two of the $\xi_{i}$'s, say $\xi_{1}$ and $\xi_{2} \neq \xi_{1}^{\tau}$ (because of
LINEARIZATION OF SYSTEMS

\[ (G_3) \text{ must cancel two of the } \alpha_i \text{'s, say } \alpha_3^* \text{ and } \alpha_4^* \text{; so we get after cancellation of } \alpha_2 + \alpha_4^* = \xi_1^* + \xi_2^* \text{ in the equality above} \]

\[ \sum_{i=5}^{4n} \alpha_i - \sum_{i=2}^{n} \mu_i - \sum_{i=2}^{n} \mu_i^* - \sum_{i=2}^{n} \mu_i^* - \sum_{i=2}^{n} \mu_i^* = \sum_{i=5}^{2n} \xi_i + \sum_{i=5}^{2n} \xi_i^* - \sum_{i=5}^{4n} \alpha_i^*, \]

which puts us in the same situation as before; so, we proceed by induction until nothing is left, concluding that among the \( \mu_i \)'s, only \( \mu_i^* + \mu_i^* \) can appear in \( D \).

Hence \( D \subseteq \sum_1^n \mu_i^* + \sum_1^n \mu_i^* \); since \( D = D^{\sigma} \) and because of \( (G_3) \), \( D = \sum_1^s \mu_i^* + \sum_1^s \mu_i^* \) for some \( 1 \leq s \leq n \); hence \( O(D) = 2s \leq 2n = g + 1 \), establishing Lemma 3.

We now turn to

**Lemma 4.** The map in Lemma 3 is one-to-one, for a possibly smaller Zariski open set in \( \mathscr{A}(X) \); moreover \( O(D) = 2n \).

**Proof.** Let two matrices \( A_h \) and \( A_h' \) in the Zariski open set defined by Lemma 3 lead to the same divisor; then we show that \( A_h \equiv A_h' \) and that \( f_k \equiv f_k' \) modulo the group action above.

To begin with, \( f_1 \) and \( f_1' \) satisfy the properties

\[ (z + a_n f_1)_{\infty} \geq P - Q \quad \text{and} \quad (z + a_n' f_1')_{\infty} \geq P - Q, \]

\[ (f_1)_{\infty} \geq -P + Q \quad \text{and} \quad (f_1')_{\infty} \geq -P + Q. \]

Hence, \( a_n f_1 - a_n' f_1' \in \mathcal{L}(D - P - Q) \). Moreover by the Riemann–Roch theorem

\[ \dim \mathcal{L}(D - P - Q) = \dim \Omega(-D + P + Q) + 2s - (2n - 1) - 1 \quad (18) \]

and

\[ -\dim \Omega(-D + P + Q) = 2(n - s), \quad (19) \]

because \( \omega \in \Omega(-D + P + Q) \) has the form

\[ \omega = R(z) y^{-1} dz, \quad y^2 = (q(z))^2 - 4A^2 \]

with \( R(z) \) a polynomial of degree at most \( g = 2n - 1 \) vanishing at the \( 2s \) distinct points in \( D \), distinct from a branch point. Therefore combining (18) and (19), \( \mathcal{L}(D - P - Q) = \{0\} \) and \( f_1' = c_1 f_1 \) with \( c_1 = a_n/a_n' \).

Since then

\[ a_n f_{-1} = z f_0 + a_n f_1 = z f_0 + a_n' f_1' = a_n' f_{-1}', \]

also \( f_{-1} \) and \( f_{-1}' \) are proportional. Next we show \( f_{2} = c_2 f_2 \); indeed, since

\[ (z f_1 + a_n f_0 + b_n f_1) \geq -2P + 2Q - D \]
and
\[
(zf'_1 + a'_n f_0 + b'_n f'_1) = (zf_1 + c'_1 a'_n f_0 + b'_n f_1) \geq -2P + 2Q - \mathcal{D},
\]
we conclude \( a_n = c_1^{-1} a'_n = a''_n a'_n^{-1} \) and \( b_n = b'_n \), i.e., \( a_n = c_1^{-1} a'_n \) and \( c_1 = +1 \); also
\[
-a_{n-1} f_0 = zf_1 + a_n f_0 + b_n f_1 = zf_1 + c_1 a'_n f_0 + b'_n f_1 = -c_1 a'_{n-1} f'_2.
\]
Proceeding in this fashion, we show that \( f'_k = c_k f_k \) for \(-n + 1 \leq k \leq n - 1\) and \( a_{n+1-k} = c_{n+1-k} a'_n \), \( c_k = \pm 1\), for \( 1 \leq k \leq n - 1\); moreover \( c_0 - 1 \) and \( c_{-k} = c_k \). Finally, \( f_{\pm n} \) and \( f'_{\pm n} \) satisfy the first (multiplied by \( h \)) and last recursion relations:
\[
(z - b'_1) f'_{n+1} = a'_{n+1} f'_{n-1} + a'_1 f'_{n+2}, \quad (z - b'_1) f'_{n+1} = a'_{n+1} f'_{n-1} + a'_1 f'_{n+2},
\]
(20)
\[
(z + b'_1) f'_{n} = -a'_{n-1} - a_{n+1} f'_{n+2}, \quad (z + b'_1) f'_{n} = -a'_{n-1} - a_{n+1} f'_{n+2},
\]
where \( f'_{n-1} = c_{n-1} f_{n-1} \) and \( f'_{n+2} = c_{n-1} f_{n+2} \). We show that the respective coefficients in the above relations and so the \( f_{\pm n}'s \) are equal modulo the group action. Remember that by \((G_1)\), \( \mathcal{D} \) does not contain \( b_1 \), \( b'_1 \), \( b_1^\sigma \), \( b'_1^\sigma \). Therefore each of the expressions on the right-hand side vanishes and breaks up as follows:
\[
a_{n+1} f_{n-1}(b'_1) + a_1 f_{n+2}(b'_1) = 0, \quad -a_{n-1}(b'_1) - a_{n+1} f_{n+2}(b_1^\sigma) = 0.
\]
(21)
\[
a_{n+1} f_{n-1}(b'_1^\tau) + a_1 f_{n+2}(b'_1^\tau) = 0, \quad -a_{n-1}(b'_1^\tau) - a_{n+1} f_{n+2}(b_1^\tau) = 0.
\]
and similarly for the primed expression. Since \( a_1 \) and \( a_{n+1} \) do not vanish, the determinant
\[
W(z) = f_{n-1}(z) f_{n-2}(z) - f_{n-1}(z) f_{n+2}(z)
\]
vanishes at \( b_1 \), \( b'_1 \), \( b_1^\sigma \) and \( b'_1^\tau \), which are all distinct by
\[
(G_4) \quad b_1 \neq 0 \text{ and } q(b_1^\sigma)^2 - 4A^2 \neq 0.
\]
Moreover
\[
(W) \geq -\mathcal{D} - \mathcal{D}^* + b_1 + b_1^\tau + b_1^\sigma + b_1^\tau - 2P - 2Q + \text{all } 4n \text{ branch points}
\]
with equality at \( P \) and \( Q \),
(22)
because
\[(f_{n-1} f_{n+2})_p = -(n - 1)P + (n + 1)P = 2P\]
and
\[(f_{n-1}^* f_{n+2})_p = (n - 1)P - (n + 1)P = -2P.\]
Therefore
\[\# \text{ of poles of } W \leq 4n + 4\]
and
\[\# \text{ of zeros of } W \geq 4n + 4;\]
hence equality. As a by-product, equality holds in (22) and \(o(\Omega) = 2n; \) therefore
\[\Omega = \sum_{i=1}^{n} \mu_i^o + \sum_{i=1}^{n} \mu_i^r.\]
For the primed equations (20), we have the same \(W(z)\) up to a constant and hence the same zeros; in particular
\[b_1 + b_1^r + b_1^o + b_1^{or} = b_1' + b_1'^r + b_1'^o + b_1'^{or}.\]
Going back to numerical values, we get that \(b_1 = \pm b_1'.\) First assume that \(b_1 = b_1'.\) Then Eqs. (21) for the primed and nonprimed quantities yield
\[\frac{a_{n+1}}{a_1} = \frac{f_{n+2}(b_1)}{f_{n-1}(b_1)} = \frac{f_{n+2}'(b_1)}{f_{n-1}'(b_1)} = \frac{a_{n+1}'}{a_1'}.\]
Let \(c = a_1'/a_1 = a_{n+1}'/a_{n+1}.\) Then
\[(z - b_1)f_{n+1}' = (z - b_1')f_{n+1}' \quad \text{because } b_1 = b_1'\]
\[= a_{n+1}' f_{n-1}' + a_1' f_{n+2}' \quad \text{by (21) for the primed relation}\]
\[= c_{n-1} c[a_{n+1} f_{n-1}(x) + a_1 f_{n+2}(x)] \quad \text{using } f_{n-1}' = c_{n-1} f_{n-1} \text{ and } f_{n+2}' = c_{n-1} f_{n+2}\]
\[= c_{n-1} c(x - b_1) f_{n+1}(x) \quad \text{by (20) for the unprimed relation}\]
and
\[(z + b_1) f_n' = (z + b_1') f_n'\]
\[= -a_1' f_{n-1}' - a_{n+1}' f_{n+2}'\]
\[= c_{n-1} c(-a_1 f_{n-1} - a_{n+1} f_{n+2})\]
\[= c_{n-1} c(x + b_1) f_n'.\]
Therefore $f'_n$ and $f'_{n+1} = hf_n'$ are proportional to $f_n$ and $f_{n+1} = hf$, respectively, with the same proportionality constant. Since

$$a'_ia'_{n+1} = \frac{A'}{\prod^n_i a'_i^2} = \frac{A}{\prod^n_i a_i^2} = a'a_{n+1}, \quad \text{as } A' = A$$

we have that $c^2 = 1$, so that $a'_i = \pm a_1$, $a'_{n+1} = \pm a_{n+1}$, and $f'_n = \pm c_n f_n$ simultaneously. Second, we assume $b_i = -b'_i$; as a result of (21) the same holds, except that in the latter relations $f_n$ and $f_{n+1}$ and also $a_i$ and $-a_{n+1}$ become interchanged. This finishes the proof of Lemma 4.

Define

$$Y = \{\mathcal{O} \mid \mathcal{O} \not\subset 0, \mathcal{O} = \mathcal{O}^\tau, o(\mathcal{O}) = 2n \} \subset Y_0.$$

**Lemma 5.** For generic curves $X$, a Zariski open set in $\mathcal{A}(X)$ maps one-to-one onto a Zariski open subset of $Y$.

**Proof.** Indeed

$$\dim \mathcal{A}(X) = \# \text{ parameters in } A_h - \# \text{ relations defining a given curve } X$$

$$\geq (2n + 1) - (n + 1) = n$$

and (see Lemma 3, for the definition of $E$).

$$\dim E \leq n;$$

since the map from $\mathcal{A}(X)$ to $E$ is one-to-one analytic, it follows that

$$\dim \mathcal{A}(X) = \dim E = n.$$

Since $E$ is a Zariski open subset in $Y$, the result follows.

We now indicate why $(G_2)$ is a generic statement; indeed from the form of the matrix $A_h$, letting $a_k \to 0$ (1 $\leq k \leq n + 1$), we see that $A_{n+1,n+1} \simeq \prod^n_{1} (z^2 - b_i^2)$ and hence for $b_i \neq 0$, the zeros of $A_{n+1,n+1}$ are all distinct on $X$, modulo the hyperelliptic involution $\tau$. Another limiting argument will show that a branch point of $X$ does not need to be a zero of $A_{n+1,n+1}$. The other generic statements follow in a similar fashion.

To conclude the proof of statement (a) of Theorem 2, we observe that by the continuous variation of the roots of a polynomial and its coefficients we may extend the map above from the Zariski open set in $\mathcal{A}(X)$ to the whole of $\mathcal{A}(X)$.

As to the linearization in (b), the proof previously given (Theorem 1) can be taken word by word; we only observe that the Lax equation preserves the form of $A$, since the polynomials $T(z)$ are taken to be of odd degree. So, any Lax flow of the type described in Theorem 1 translates into a flow

$$\sum_{l=1}^{2n} \int_{\nu_{l}(t)}^{\nu_{l}(0)} \omega_k = t \text{ Res}_{t}(\omega_k T(x))$$

(which vanishes for $k$ even),
which automatically preserves \( Y \) by (a). To see that \( J \) is the embedding of \( Y \) in \( \text{Jac}(X) \), observe that any divisor \( \mathcal{D} = \mathcal{D}^a + \mathcal{D}^\sigma \) in \( E \) trivially satisfies

\[
\mathcal{D} + \mathcal{D}^a = 0 \text{ in } \text{Jac}(X)
\]

with a \( \tau \)-invariant base point. By closing up \( Y \), this shows that \( Y \) embeds in \( J \). In fact \( \dim Y = \dim J \), because \( \dim Y = n \); indeed the condition \( \mathcal{D} + \mathcal{D}^a = 0 \) in \( \text{Jac}(X) \) is trivially satisfied for \( \omega_k = x^{k-1}y^{-1}dx \) for \( k \) odd; so, also

\[
Y = \left\{ \mathcal{D} \mid \mathcal{D} \geq 0, 0(\mathcal{D}) = 2n, \int \mathcal{D} \omega_k + \int \mathcal{D}^\sigma \omega_k = 0, k \text{ even} \right\}
\]

and \( \dim Y = g - (n - 1) = n \). This concludes the proof of Theorem 2.

**Remark.** From the arguments above we cannot exclude the fact that \( \mathcal{A}(X) \) is a multiple covering of \( J \).

**Sketch of proof of Theorem 1 (so(n, n)).** The hyperelliptic curve \( X \) is defined by (see I (4.27))

\[
Q(z, h) = \det(A_h - zI) = 4Az^2(h + h^{-1}) + (-1)^n g(z^2) = 0,
\]

where \( A = a_i a_{n+1} a_{n-1} a_n \prod_{k=2}^{n-2} a_k^2 \) and \( g \) is a monic polynomial of degree \( n \). The curve \( X \) has the same involutions \( \tau \) and \( \sigma \) as before and again \( g = 2n - 1 \); the functions \( h \) and \( z \) clearly have the divisors given in the statement of the theorem. The eigenvector \( f = (f_1, \ldots, f_{2n})^t \) of \( A \) with \( f_1 = 1 \) can be extended by the formula

\[
hf_k - f_{k+2n}, \quad j \in \mathbb{Z},
\]

to an infinite vector. The meromorphic functions

\[
f_k = \frac{A_{1,k}}{A_{1,1}} = \frac{A_{k,k}}{A_{k,1}}
\]

have the properties

\[
(f_k) \geq -\mathcal{D} - (k - 1)P + (k - 1)Q, \quad 1 \leq k \leq n
\]

\[
-\mathcal{D} - (k - 2)P + (k - 2)Q, \quad n + 1 \leq k \leq 2n
\]

with equality at \( P \) and \( Q \), (23)

where \( \mathcal{D} \) is a positive divisor in \( Y \) and is minimal with regard to (23). The proof of this statement follows, roughly speaking, the same lines as those for Theorem 2; we shall point out the relevant difference: the structure of the divisor \( \mathcal{D} \) is generically\(^8\) given by the divisor of \( f_{2n} \) on \( X_0 \):

\^[8\] All generic statements can be taken care of as in Theorem 2.
\[
(f_{2n})_0 = \left( \frac{A_{1,2n}}{A_{2n,2n}'} \right)_0 = (\mathcal{E}_1 + \mathcal{E}_2 + \mathcal{E}_1^\sigma + \mathcal{E}_2^\sigma) - (\mathcal{D}_1 + \mathcal{D}_2 + \mathcal{D}_1^\tau + \mathcal{D}_2^\tau)
\]
\[
= \left( \frac{A_{1,1}}{A_{2n,1}} \right)_0 = (\mathcal{D}_2^\sigma + \mathcal{D}_2^\sigma + \mathcal{D}_1^\sigma + \mathcal{D}_2^\sigma) - (\mathcal{E}_1^\tau + \mathcal{E}_2^\tau + \mathcal{E}_1^\sigma + \mathcal{E}_2^\sigma),
\]

where \(\mathcal{E}_i\) and \(\mathcal{D}_i\) are positive divisors of order \(n\); this is a consequence of the facts: \(A_{11}' = A_{2n,2n}'\), \(A_{1,2n}' = A_{2n,1}'\). Only the formal aspect of the argument will be given; as in the previous case, an induction argument is necessary. If no cancellation occurs in (24), we may assume without loss of generality that \(\mathcal{D}_1 = \mathcal{E}_1^\tau\), which implies cancellation does occur and so we shall in fact assume \(\mathcal{D}_1 = \mathcal{E}_1^\tau\), which leaves us with the relation above without the index 1. So we start again, assuming \(\mathcal{D}_2 = \mathcal{E}_2^\tau\); from the above, we conclude \(\mathcal{D} = \mathcal{D}_1 + \mathcal{D}_2 = \mathcal{E}_1^\tau + \mathcal{E}_2^\tau\) and so we have

\[
(A_{2n,2n}) = \mathcal{D} + \mathcal{D}^\tau - (2n - 1)P - (2n - 1)Q - R - S
\]
and

\[
(A_{1,2n}) = \mathcal{D}^\tau + \mathcal{D}^\tau^o - (4n - 3)P - Q - 3R + S;
\]

therefore taking the difference of their corresponding Abelian sums \(\mathcal{D} - \mathcal{D}^\tau = (h) \equiv 0\), which shows that \(\mathcal{M}(X)\) maps into \(Y\).

We now sketch the uniqueness argument; we show that two matrices \(A_h\) leading to the same divisor \(\mathcal{D}\) are equal modulo the group action, i.e., that the \(a_k\)'s and \(b_k\)'s are uniquely defined by \(A_hf = zf\). In particular, because of (4.27),

\[
-a_1f_{-1} - a_{n+1}f_2 = (z + b_1)f_0,
\]
\[
a_{n+1}f_{-1} + a_1f_2 = (z - b_1)f_1 \quad (f_1 = 1);
\]

we first determine \(b_1\) and the ratio \(\alpha = a_1/a_{n+1}\). Letting \(g_{-1} = a_{n+1}f_{-1}\) and \(g_2 = a_1f_2\), we rewrite the linear equations above as

\[
\alpha g_{-1} + \alpha^{-1}g_2 = -(z + b_1)f_0, \quad (25)
\]
\[
g_{-1} + g_2 = (z - b_1); \quad (26)
\]

from (26) and the generic statements\(^9\) \(\dim \mathcal{L}(\mathcal{D} - P - Q) = 0\), \(\dim \mathcal{L}(\mathcal{D} - Q) = 1\), \(\dim \mathcal{L}(\mathcal{D} - P) = 1\), \(\dim \mathcal{L}(\mathcal{D} - 2Q) = 0\), \(\dim \mathcal{L}(\mathcal{D} - 2P) = 0\), it follows that \(g_2\) and \(g_{-1}\) can be uniquely written as an identity in \(b_1\):

\[
g_2(x) = \tilde{g}_2(x) - b_1\tilde{h}_2(x),
\]
\[
g_{-1}(x) = \tilde{g}_{-1}(x) - b_1\tilde{h}_{-1}(x), \quad (27)
\]

\(^9\) Their genericity is proved in a fashion similar to that in Theorem 2.
where the functions are uniquely determined by the relations
\[
\begin{align*}
(\ell_2)_0 &= -P + Q, \\
(\ell_2 - z)_P &\geq P, \\
(\ell_2)_0 &\geq -\mathcal{D} \\
(h_2)_0 &= Q, \\
(h_2 - 1)_P &\geq P, \\
(h_2)_0 &\geq -\mathcal{D} 
\end{align*}
\]
and similarly for \( \ell_{-1} \) and \( h_{-1} \) with \( P \) and \( Q \) interchanged. Equation (25) will now be used to determine \( b_1 \) and \( \alpha \). As before, we make the generic assumption that \( b_1 \) and \( b_1^* \) are not in \( \mathcal{D} \). Therefore from (25)
\[
\alpha g_{-1}(-b_1) + \alpha^{-1} g_2(-b_1) = 0,
\]
which implies that
\[
\alpha g_{-1}(b_1^*) + \alpha^{-1} g_2(-b_1^*) = 0,
\]
and hence
\[
(W(z) - \mathcal{D} - \mathcal{D}^* + b_1 + b_1^* + b_1^* - 2P - 2Q + \text{all 4n branch points})
\]
vanishes at \(-b_1\) and \(-b_1^*\). From a similar argument where \( f_0 \) is normalized at 1, instead of \( f_1 \) (thus the roles of \( f_0 \) and \( f_1 \) and \( b_1 \) and \(-b_1\) are interchanged), we have that \( W(z) \) also vanishes at \( b_1 \) and \( b_1^* \). Moreover from (28),
\[
(W(z))_0 - \mathcal{D} - \mathcal{D}^* + b_1 + b_1^* + b_1^* - 2P - 2Q + \text{all 4n branch points}
\]
and hence equality; then we conclude \( o(\mathcal{D}) = 2n \) and the zeros of \( W(z) \) are precisely the zeros specified. Therefore \( \alpha \) is determined uniquely by (29) and so is \( f_0, g_{-1}, g_2 \). Using the next relation in the set of relations \( A_h f = z f \), one shows that \( f_2 \) is uniquely determined up to a constant factor by an argument similar to Lemma 4 and in the fashion for \( f_k \ (n - 2 \leq k \leq n + 1) \). First by the periodicity relations \( h f_k = f_{k+2n} \) for \( -n - 2 \leq k \leq n \), are determined. Using the \( n \)th and \((n + 1)\)th relation in \( A_h f = z f \), and by an argument precisely the same as that used to determine \( f_n \) and \( f_{n+1} \) in Lemma 4, we see that indeed \( f_n \) and \( f_{n+1} \) are uniquely determined (modulo the group action). We have thus determined the \( f_i \) uniquely up to the map \( f_i \rightarrow c_i f_i \); however, the symmetry of the \( A_h \) shows that \( c_i^2 = c_j^2 \) for all \( i, j \), hence the matrix \( A_h \) is indeed uniquely determined modulo the group action. The linearization argument proceeds exactly as for \( sl(n) \) with the modifications made for \( so(n)\).
so we need only prove the statement concerning $Y$ and $J$. The argument is done as follows: let $N = 2n$; in view of

$$f_1 = \frac{A_{N1}}{A_{NN}} = \frac{A_{11}}{A_{1N}} \quad (f_N = 1)$$

and $A_{N1}^e = A_{1N}^e$, $A_{ii}^e = A_{ii}$, $A_{NN}^e = A_{NN}$ we have that generically for some divisors $\mathbb{D}$ and $\mathbb{E}$ of order $g$

$$(A_{IN})_0 = \mathbb{D} + \mathbb{D}^a, \quad (A_{N1})_0 = \mathbb{D}^r + \mathbb{D}^{ra},$$

$$(A_{NN})_0 = \mathbb{E} + \mathbb{E}^r, \quad (A_{11})_0 = \mathbb{E}^a + \mathbb{E}^{ra},$$

from which it follows from an argument previously given that, possibly after relabeling, one has $\mathbb{D} = \mathbb{E}$ and $\mathbb{D}$ is minimal. Therefore by Abel's theorem applied to

$$(A_{IN}) = \mathbb{D} + \mathbb{D}^a - 2gP$$

we have for $\mathbb{D} = \sum \mu_i$

$$\sum \int \mu_i \omega + \sum \int \mu_i^a \omega = 0,$$

which proves the assertion concerning $Y$. Nothing is special about the linearization.

**Proof of Theorem 1 for $G_2$.** From the considerations in I, Section 4, the matrix $A_h$ is treated with the $so(3,4)$ case; however one checks that there are three curve invariants, hence dim $\mathcal{A}(X) = 2$, while dim $Y$ for $SO(3,4)$ equals 3, and $soA(X)$ maps onto a two-dimensional subvariety of $Y$, which moreover is linear by the fact that two independent linear flows on $J$ preserve it. We also note that by the considerations in $so(3,4)$, any linear flow is given by a specific odd polynomial of degree at most five. Since from the Lie algebra considerations, $z$ leads to a linear flow on the subvariety $J$ corresponding to the $G_2$ case, another independent flow must be generated by a specific linear combination of $z^3$ and $z^5$.

3. **Linearization of Flows of Spinning Top Type**

In I, Section 4, various problems were shown to be related to isospectral deformations of polynomials with matrix coefficients

$$A = \sum_{i=0}^v A_i h^i.$$ 

For such matrix polynomials we have the following theorem.

$^\text{10} \quad \varepsilon^k = (\delta_{ik})_{1 \leq i \leq n}.$
THEOREM 1. There is a one-to-one correspondence between

(i) a polynomial $A = \sum_{i=0}^{n} A_i h^i$ with matrix coefficients (modulo conjugation by complex diagonal matrices), having the property $A = \text{diag}(a_1, \ldots, a_n)$, $a_i \in \mathbb{C}$, $\prod_{i \neq j} (a_i - a_j) \neq 0$, and $(A_{r-1})_{r-k} \neq 0$ ($k \neq 1$); moreover $A$ has in the limit $h \to 0$ distinct eigenvectors all not perpendicular to $e_k$ for some $k$.

(ii) a curve $X$ of genus $g = (n(n-1)/2) + n + 1$ with $2n$ distinct points $P_1, \ldots, P_n$, $Q_1, \ldots, Q_n$ and a general positive divisor $D$ on $X$ of degree $g$ not containing any of the points $P_i$ or $Q_i$; the points above have the following properties: for some meromorphic functions $h$ and $z$ on $X$

$$(h) = -\sum_{i=1}^{n} P_i + \sum_{i=1}^{n} Q_i$$

and

$$(z) = -\nu \sum_{i=1}^{n} P_i + n\nu \text{ zeros, distinct from the } P_i.$$ 

Moreover any polynomial function $u = P(x, h, h^{-1})$ on $X$ leads to an isospectral deformation of $A$

$$A = [A, P(A, h, h^{-1})],$$

where $P(A, h, h^{-1})$ denotes the polynomial part (in $h$) of $P(A, h, h^{-1})$. The flow above is a linear flow on $\text{Jac}(X)$ defined by

$$\sum_{i=1}^{g} \int_{\gamma_i} \omega = \sum_{i=1}^{n} \text{Res}_i(\omega u) t.$$ 

In particular the flows (cf. I (4.43))

$$\dot{A} = [A, (f'(Ah^{-1})h^{k-1})],$$

are linear flows on $\text{Jac}(X)$; they are equivalent to one of the polynomial flows above.

Proof. As a first step, the curve $X$, defined by the algebraic equation

$$Q(x, h) = \det(A - xI),$$

is shown to have the properties stated in (ii). For $z, h$ large,

$$Q(x, h) = \prod_{i=1}^{n} (a_i h^v - z) + C_1 h^{n-1} + C_2 z^{n-1} + \text{lower-order terms},$$

whence, using the local parameter $t = h^{-1}$ at $\infty$,

$$z = a_i t^{-\nu} + \text{lower-order terms}, \quad 1 \leq i \leq n.$$ 

Therefore, covering $\infty$, there are $n$ distinct branch points $P_1, \ldots, P_n$ of order $\nu - 1$. The spectrum of $A$, in the limit $h \to 0$, defines $n$ distinct points $Q_1, \ldots, Q_n$. So,

$$(h) = -\sum_{1}^{n} P_i + \sum_{1}^{n} Q_i$$

and

$$(z) = -\nu \left( \sum_{1}^{n} P_i \right) + n\nu \text{ zeros, distinct from the points } P_i.$$ 

So, the ramification index $V_\infty$ at $\infty$ over $z$ equals

$$V_\infty = n(\nu - 1),$$

while the ramification index $V_0$ for the affine part equals the total order of pole of the expression

$$\left. \frac{\partial Q}{\partial h} \right|_{P_i} = \frac{d}{dh} \prod_{j} (z - a_j h^\nu) \bigg|_{P_i} + \text{lower-order terms}$$

$$= -a_i h^{\nu - 1} \prod_{j \neq i} (z - a_j h^\nu) + \text{lower-order terms}$$

at the points $P_i$ ($1 \leq i \leq n$), i.e.,

$$V_0 = n((\nu - 1) + (n - 1)\nu).$$

Hence

$$V = V_0 + V_\infty = n(\nu - 1) + n((\nu - 1) + (n - 1)\nu) = 2n\nu + 2g - 2.$$ 

and

$$g = \frac{n(n - 1)}{2} \nu - n + 1. \quad (1)$$

Let $\phi^s$ be the eigenvector of $A$ near the points $P_s$, normalized at $(\phi^s)_0 = 1$. Since, at $P_s$, the spectral problem reads

$$(A h^{-\nu}) e^s - a_s e^s, \quad h \to \infty,$$

$\phi^s$ can be expanded around $e^s$ and $z h^{-\nu}$ around $a_s$,

$$\phi^s(t) = e^s + vt + O(t^2) \quad \text{with} \quad v \in C^n, \quad v_s = 0, \quad \text{and} \quad O(t^2)_s = 0,$$
and

$$zh^{-v} = a_s + b_s t + O(t^2).$$

To find $v$ and $b_s$, set up the spectral problem

$$(A_s + A_{s-1} t + O(t^3))(e^s + vt + O(t^2))$$

$$= (a_s + b_s t + O(t^2))(e^s + vt + O(t^2)),$$

which to the first order yields the linear equation

$$A_{s-1} e^s + A_s v = a_s v + b_s e^s$$

or, componentwise,

$$(A_{s-1})_{is} + a_s v_i = a_s v_i, \quad i \neq s.$$ 

Therefore, solving for $v_i,$

$$(\phi^s)_i = \frac{(A_{s-1})_{is}}{a_s - a_i} t + O(t^2), \quad i \neq s,$$

$$= 1, \quad i = s.$$ 

Consider now the eigenvector $f = (f_1, \ldots, f_n)^t$ of $A$, normalized at $f_1 = 1$, at each of the points $P_s$; then

$$k \neq 1 \quad f_k = \frac{\phi^s_k}{\phi^s_1} = \frac{(A_{s-1})_{1s}}{a_1 - a_s} t + O(t^3) \quad \text{at } P_1$$

$$= \frac{(A_{s-1})_{is}}{(A_{s-1})_{1s}} \cdot \frac{a_s - a_1}{a_s - a_k} + O(t) \quad \text{at } P_s, s \neq k,$$

$$= \frac{a_s - a_1}{(A_{s-1})_{1s}} t^{-1} + O(1) \quad \text{at } P_k,$$

which makes sense, since by assumption $(A_{s-1})_{1s} \neq 0$ for $s \neq 1$ and $\prod_{i \neq s} (a_i - a_s) \neq 0$. Therefore

$$(f_k)_1 \geq P_1 - P_k \quad \text{with equality at } P_k.$$ 

Let $\mathcal{D}$ be the minimal positive divisor such that

$$(f_k)_{\infty} = -\mathcal{D} + P_1 - P_k, \quad 1 \leq k \leq n.$$

\footnote{\( (\cdot)_1 = (\cdot)_{\mathcal{P}_1} \).}

$607/383/3-8$
Neither of the points $P_j$ or $Q_j$ appears in $\mathcal{D}$. If $\mathcal{D}$ contained $P_j$ then

$$(f_k) \geq -(\mathcal{D} - P_j) + P_1 - P_k$$

because $f_k$ never has a pole at $P_j$ ($j \neq k$) and has a pole of order 1 at $P_k$. Then $\mathcal{D}$ would not be minimal. If $\mathcal{D}$ contained $Q_j$, then at least one of the $f_k$'s would have to have a pole at $Q_j$. This is impossible, because the eigenvector of $A$, when $h \to 0$, has a nonzero first component by assumption. In general, for any $k + \alpha n \in \mathbb{Z}$

$$f_{k+\alpha n} = h^\alpha f_k$$

and

$$(f_{k+\alpha n}) \geq -\mathcal{D} + P_1 - P_k + \alpha \sum_{i=1}^{n} (Q_i - P_i).$$

The proof that $\mathcal{D}$ is general or, equivalently, $\dim \mathcal{L}(\mathcal{D}) = 1$ follows the lines of Moerbeke and Mumford [16]; consider the spaces

$$R = \frac{\mathbb{C}[h, h^{-1}, z]}{Q(h, z)} \subseteq \mathcal{L}_1 = \text{linear span of } f_k's \subseteq \mathcal{L} = \{f \text{ meromorphic with } (f) + \mathcal{D} \geq \text{any linear combination of } P_k \text{ and } Q_k \text{ with } k \in \mathbb{Z}\}.$$.

Since $\mathcal{L}_1$ is an $R$-module (indeed $zf_k$ and $hf_k \in \mathcal{L}_1$), $\mathcal{L}_1 = \mathcal{L}$ must hold, because otherwise all functions in $\mathcal{L}$ would vanish at some point $p \in X$, which $1 \in \mathcal{L}_1$ clearly violates. Hence any function of $f \in \mathcal{L}(\mathcal{D})$ is a linear combination of $f_k$'s; no $f_k$ with $k \geq 2$ can occur, because any such linear combination would always have at least a pole at the points $P_k$; therefore

$$f = b_1 f_1 + h^{-1} \left( \sum_{i=1}^{n} f_i b_i^{1} \right) + \cdots + h^{-\alpha} \left( \sum_{i=1}^{n} f_i b_i^{n} \right), \quad \alpha \geq 1,$$

and

$$fh^{\alpha}(Q_j) = b_1 f_1 h^{\alpha}(Q_j) + h^{-1} \left( \sum_{i=1}^{n} b_i f_1(Q_i) \right) + \cdots + h^{-\alpha} \sum_{i=1}^{n} b_i f_i(Q_j), \quad 1 \leq j \leq n,$$

i.e.

$$\sum_{i=1}^{n} b_i f_i(Q_j) = 0, \quad 1 \leq j \leq n.$$.

Now, it is assumed that the eigenvectors of $A$, in the limit $h \to 0$, are distinct. Hence the $n$ eigenvectors $(f_i(Q_j))_{1 \leq i \leq n}$ are independent and $\det(f_i(Q_j))_{1 \leq i, j \leq n} \neq 0$, implying $b_i^2 = 0$, $1 \leq i \leq n$. In the same way $b_i^1 = 0$ for $1 \leq i \leq n$, $1 \leq j \leq \alpha$, proving that $f = b_1 f_1 = b_1$. Therefore $\mathcal{L}(\mathcal{D}) = \{\text{constants}\}$ and $\dim \mathcal{L}(\mathcal{D}) = 1$. 
To show that \( o(\mathcal{D}) = g \), we show that \( \dim \mathcal{L}(\mathcal{D}) = ni + 1 \) for \( \mathcal{D} = \mathcal{D} + i \sum_{k} P_k \) with \( i \) large enough. Clearly \( \dim \mathcal{L}(\mathcal{D}) \geq ni + 1 \), since every function \( f_k \) (\( 1 \leq k \leq ni + 1 \)) belongs to that space. But every function \( f \in \mathcal{L}(\mathcal{D}) \) is a linear combination of \( f_k \)'s (\( 1 \leq k \leq ni + 1 \)), because at each \( P_n \) it has a pole of order at most \( i \). Therefore, since \( \dim \Omega(-\mathcal{D}) = 0 \), by Riemann–Roch

\[
ni + o(\mathcal{D}) - g + 1 = \dim \mathcal{L}(\mathcal{D}) = ni + 1
\]

and

\[
o(\mathcal{D}) = g.
\]

Conversely, let \( \mathcal{D} \) be a general divisor not containing \( P_i \)'s or \( Q_i \)'s on the curve \( X \) as described in (ii). Then

\[
1 \leq \dim \mathcal{L}(\mathcal{D} - P_1 + P_k) \leq \dim \mathcal{L}(\mathcal{D} - P_1) + 1 = 1;
\]

the first inequality is a consequence of Riemann–Roch, the second a consequence of the fact that adding a pole increases the dimension by at most one, and the third (equality) a consequence of the fact that \( \dim \mathcal{L}(\mathcal{D}) = 1 \). Then the unique function \( f_k \in \mathcal{L}(\mathcal{D} - P_1 + P_k) \) must have a pole of exact order one at \( P_k \), because otherwise \( f_k \neq \text{constant} \) would belong to \( \mathcal{L}(\mathcal{D}) \), contradicting \( \dim \mathcal{L}(\mathcal{D}) = 1 \). Then

\[
(zf_k) \geq -\mathcal{D} - (\nu - 1)P_1 - \nu \sum_{i \neq 1} P_i - (\nu + 1)P_k
\]

with equality at \( P_k \). Then, for some \( a_k \in \mathbb{C}^* \)

\[
(zf_k - a_k h^s f_k) \geq -\mathcal{D} - (\nu - 1)P_1 - \nu \sum_{i \neq 1} P_i.
\]

From the expression in brackets, subtract some multiple of \( h^s f_j \) (\( j \neq 1 \)) if it has a pole of exact order \( \nu \) at some \( P_j \) (\( j \neq 1 \)). Proceeding in this way, \( zf_k \) is seen to be expressible as a linear combination

\[
zf_k = a_k h^s f_k + \sum_{i=0}^{\nu-1} h^s \sum_{j=1}^{n} (A_{ij}) f_j
\]

defining a matrix

\[
A = A_k h^s + \sum_{k=0}^{\nu-1} A_k h^s, \quad A_k = \text{diag}(a_1, \ldots, a_n), \quad \prod_{1}^{n} a_k \neq 0.
\]

Also, \( \prod_{i<j} (a_i - a_j) \neq 0 \) must hold, because otherwise the \( n \) points \( P_1, \ldots, P_n \) would not be distinct. Moreover \( (A_{k-1})_{1,k} \neq 0 \) (\( k \neq 1 \)), because otherwise \( f_j \) (\( 2 \leq j \leq n \)) would not have a pole of order higher than 1 at \( P_j \). Finally \( A_0 \) must
have in the limit distinct eigenvalues, for otherwise the points $Q_i$ would not be distinct. The divisor $\mathcal{D}$ not containing $Q_i$'s forces the $A_0$ eigenvectors to all have non-zero components.

Note that since the functions $f_k$ can be multiplied with a scalar, the matrix $A$ is determined modulo conjugation by diagonal matrices.

As in Moerbeke and Mumford [16], the isospectral flows derive from polynomials $u$ in $z$, $h$ and $h^{-1}$, which admit the splitting

$$u = uf_1 = \sum_{i=1}^{n} c_i f_i + \sum_{i=N}^{N'} c_i f_i = g_- + g_+.$$  

Abel's theorem applied to the functions $1 + tg_+$ and $1 - tg_-$ for small $t$ leads to

$$\sum_{1}^{n} \int_{P_{i}} \omega = -\sum_{1}^{n} \int_{Q_{i}} \omega = t \sum \text{Res}_{P_{i}} \omega u + O(t^2)$$

and

$$\sum_{1}^{n} \int_{P_{i}} \omega = -\sum_{1}^{n} \int_{Q_{i}} \omega = -t \sum \text{Res}_{Q_{i}} \omega u + O(t^2),$$

where $\mathcal{D}(t) = \sum_{1}^{n} v_{i}(t)$ in the divisor of zeros of $1 + tg_+$ and $\mathcal{D}'(t) = \sum v_i'(t)$ of $1 - tg_-$. For the function $f_k(t)$ associated with the divisor $\mathcal{D}(t)$,

$$((1 + tg_+) f_k(t)) \geq -\mathcal{D} - \sum P_i + \sum Q_i,$$

where the sum in $\sum P_i$ extends to those $P_i$ as if $(1 + tg_+)$ were replaced by $u$. Let $f = (f_1, ..., f_n)^t$; then

$$(1 + tg_+) f_k(t) = \sum_{s=0}^{\mu} (B_s f)_s h^s$$

and

$$(1 - tg_-) f_k(t) = \sum_{s=-\mu'}^{1} (B_s f)_s h^s$$

for some matrices $B_s$. Comparing the two formulas and using the fact that $g_+ + g_- = u$, we have that

$$\left( \sum_{s=0}^{\mu} h^s B_s \right)_{k_1} = tC[u]_{k_1} = t(P(A, h, h^{-1})_{k_1}.$$  

Moreover, for any basis $(\omega_k)_{1 \leq k \leq \phi}$ of holomorphic differentials, we have that

$$\left\{ \left( \sum_i \text{Res}_{P_i}(u \omega_k) \right)_{1 \leq k \leq \phi} \mid u \in \mathbb{C}[z, h, h^{-1}] \right\} = \mathcal{C}$$
because the polar part of $u$ at $P_i$ can be prescribed by allowing arbitrarily large poles at the points $Q_i$. This implies that every linear flow on $\text{Jac}(X)$ can be obtained by the right choice of $u \in C[z, \hbar, \hbar^{-1}]$. Remark that, after possible cancellation, $u$ must contain $\hbar^{-1}$ in order for the flow to be nontrivial.\textsuperscript{13}

From the group theoretical argument (1), the dimension of the orbit corresponding to $A$ equals $n(n - 1)v$, implying the existence of $n(n - 1)v/2$ independent Hamiltonian flows. The set of coefficients of the polynomial $Q(z, \hbar)$ provides a basis for these Hamiltonians:

(i) $g = [n(n - 1)/2]v - (n - 1)$ among these coefficients lead to independent flows on the orbit modulo conjugation by diagonal matrices, according to the argument above.

(ii) The flows on $A$ generated by conjugation by diagonal matrices can be spanned by the flows

$$A = [A, \text{diag}(a_k^1, ..., a_k^n)]; \quad k = 1, ..., n - 1.$$  

They are independent since

$$\det \begin{pmatrix} 1 & a_1 & \cdots & a_1^{n-1} \\ 1 & a_2 & \cdots & a_2^{n-1} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & a_n & \cdots & a_n^{n-1} \end{pmatrix} = \prod_{i < j} (a_i - a_j) \neq 0.$$  

These flows derive from the Hamiltonians (see I (3.6)) $\langle (A\hbar^{-1})^k, \hbar^v \rangle_1 k = 2, ..., n$, which are among the coefficients of $Q(z, \hbar)$.

This finishes the proof of Theorem 1.

**Corollary.** Any smooth function of the Hamiltonians, appearing as coefficients of $Q(z, \hbar)$, leads to a linear flow on $\text{Jac}(X)$.

**Proof.** Let $\lambda_1, ..., \lambda_N$ be the set of coefficients of the polynomials $Q(z, \hbar)$; then for any function $H = H(\lambda_1, ..., \lambda_N)$, the vector field, defined by

$$X_H(g) = \{g, H\}$$  

can be written

$$X_H(g) = \sum_{i=1}^{N} \{g, \lambda_i\} \frac{\partial H}{\partial \lambda_i} (g) = \sum_{i=1}^{N} \frac{\partial H}{\partial \lambda_i} X_{\lambda_i}(g).$$  

Since the $\lambda_i$'s are constants of the motion, $\partial H/\partial \lambda_i$ are also constants of the motion; therefore $X_H$ is a constant linear combination of the vector fields defined by $\lambda_1, ..., \lambda_N$.

\textsuperscript{13} The linearization argument of Theorem 1 could have also been used, but the one given here proves more as it does not assume the Lax equation but in fact deduces it.
EXAMPLE. In view of later applications, it is more practical to choose for Hamiltonians nonpolynomial functions of $A$. For instance the Hamiltonian $\langle f(Ah^{-1}), h^{\nu+1} \rangle_1$ with

$$f(x) = [2/(\nu + 2)]x^{(\nu+2)/2}$$

leads to the linear flow generated by

$$(A^{1/\nu})^+ = A^{1/\nu}h + \Gamma = Bh + \Gamma,$$

where (see I (4.44))

$$\Gamma = \text{ad}_B \text{ad}_{A_0}^{-1}((I - P_D) A_{\tau^{-1}}) + (\nu/2)(A_0)^{\nu/2-1} P_D(A_{\tau^{-1}})$$

We now discuss several special cases of physical or geometrical interest:

1. $A = A_1h + A_0$ with $A_0 + A_0^* = 0$ and the Properties of Theorem 1

The set of such isospectral matrices maps one-to-one onto the general points $\mathcal{D}$ of the $[(n - 1)^2/4]$-dimensional variety in $\text{Jac}(X)$ defined by the relations

$$\int_{\mathcal{D}} \omega = 0 \quad \text{for} \quad \omega^\tau = \omega,$$

where $\tau$ is the involution

$$(z, h) \rightarrow (-z, -h).$$

The only flows preserving the antisymmetry of $A_0$ are those for which $u^\tau = -u$, i.e., linear combinations of $z^ih^{-k}$ such that $i + k$ is odd; they linearize on $\text{Prym}(X)$. In particular, the flow generated by the Hamiltonian $H = \frac{\nu}{2} \langle (Ah^{-1})^{\nu/2}, h^3 \rangle_1$, namely,

$$A = [A, ((Ah^{-1})^{1/2}h)_i] = [A_0 + A_1h, E + \beta h]$$

(Euler's rigid body motion), where $\beta = A_1^{1/2} = \text{diag}(a_1^{1/2}, \ldots, a_n^{1/2})$ and $E_{ij} = (\beta_i + \beta_j)^{-1}(A_0)_{ij}$, linearizes on $\text{Prym}(X)$.

Proof. The map $\tau$ is an involution on the curve $X$, because whenever

$$\det(A_1h + A_0 - zI) = 0,$$

we have that

$$\det(-A_1h + A_0 + zI) = \det(-A_1h + A_0 + zI)^\tau = \det(-A_1h - A_0 + zI)$$

$$= (-1)^n \det(A_1h + A_0 - zI) = 0.$$
similar to the one in Moerbeke and Mumford [16, Sect. 3, Theorem 2] leads to the fact that

\[ (A_{NN}) = \mathcal{D} + \mathcal{D}^* + \text{poles at } P_i \text{ and } Q_i. \]

Therefore, from Abel's theorem, the following relation holds for some choice of origin and for every holomorphic differential,

\[ \int_{\mathcal{D}} \omega + \int_{\mathcal{D}^*} \omega = 0. \tag{2} \]

It is trivially satisfied for the holomorphic differentials \( \omega \) such that \( \omega^* = -\omega \) and leads to genuine relations for the ones such that \( \omega^* = \omega \). Now, the dimension of their space (i.e., with \( \omega^* = \omega \)) is \( g_0 \)-dimensional, where \( g_0 \) is the genus of the quotient curve \( X_0 = X/\tau \). Therefore the variety of divisors \( \mathcal{D} \subset \text{Jac}(X) \) satisfying (2) is \( (g - g_0) \)-dimensional; let it be \( \text{Prym}(X) \). Conversely, every general divisor in \( \text{Prym}(X) \) leads to a matrix \( A = A_h + A_0 \) with \( A_0 + A_0^* = 0 \), modulo conjugation by diagonal matrices with entries \( \pm 1 \).

We now compute \( g_0 \). To begin with,

\[ Q(h, z) = \prod_{1}^{n} (a_i h - z) + Q_{n-2}(a_i h - z, ..., a_n h - z) + \cdots = 0, \]

where \( Q_k(t_1, ..., t_n) \) are homogeneous polynomials in \( t_i \) (\( 1 \leq i \leq n \)) of degree \( k \). The substitution \( t = h/z \) turns the equation above into

\[ z^n \prod_{1}^{n} (a_i t - 1) + z^{n-2}Q_{n-2}(a_i t - 1, ..., a_n t - 1) + \cdots + Q_0 = 0 \quad \text{for } n \text{ even} \]

\[ + \cdots + zQ_1 = 0 \quad \text{for } n \text{ odd}. \]

In the even (resp. odd) case, the curve \( X_0 \) is obtained by putting \( u = z^2 \) in the latter equation

\[ u^{n/2} \prod_{1}^{n} (a_i t - 1) + u^{(n-2)/2}Q_{n-2}(a_i t - 1, ..., a_n t - 1) + \cdots + Q_0 = 0 \quad \text{(3)} \]

(resp. \( u^{(n-1)/2} \prod_{1}^{n} (a_i t - 1) + u^{(n-3)/2}Q_{n-2}(a_i t - 1, ..., a_n t - 1) + \cdots + Q_1 = 0 \)); it is a \([n/2]\)-sheeted covering of the \( t \)-plane with branch points at the zeros of the discriminant

\[ \Delta = [n/2]u^{(n-3)/2} \prod_{1}^{n} (a_i t - 1) + \left[ \frac{n-2}{2} \right] u^{(n-4)/2}Q_{n-2}(a_i t - 1, ..., a_n t - 1) + \cdots \]

and possibly also at the poles of \( \Delta \). Dividing (3) by \( \prod_{1}^{n} (a_i t - 1) \), we find that, near \( t = \infty \), it reads
\[ u^{n/2} + \left( \frac{A_1}{t^2} + \cdots \right) u^{n/2-1} + \left( \frac{B_1}{t^4} + \cdots \right) u^{n/2-2} + \cdots + \frac{L_1}{t^n} = 0 \]

(resp. \( u^{(n-1)/2} + \left( \frac{A_1}{t^2} + \cdots \right) u^{(n-1)/2-1} + \left( \frac{B_1}{t^4} + \cdots \right) u^{(n-1)/2-2} + \cdots + \frac{L_1}{t^{n-1}} + \cdots = 0 \)).

Therefore \( u \) has the following expansion with generically distinct constants \( C_i \)

\[ u = C_i \frac{1}{t^i} + O \left( \frac{1}{t} \right), \quad 1 \leq i \leq \left\lfloor \frac{n}{2} \right\rfloor, \quad t \text{ near } \infty; \]

So, \( u \) has a double zero at \( \left\lfloor n/2 \right\rfloor \) points, labeled \( R_i \). Moreover, the function \( u \) has a simple pole at \( t = a_i^{-1} \) (1 \( \leq i \leq n \)). So \( \Delta \) has poles at

\[ 2 \sum_{i=1}^{n/2} R_i + \frac{n-4}{2} \sum_{i=1}^{n} P_i \]

and therefore vanishes at

\[ \frac{n(n - 4)}{2} + n = \frac{n(n - 2)}{2} \quad \text{ (resp. } \frac{n(n - 5)}{2} + \frac{3(n - 1)}{2} = \frac{n(n - 2) - 3}{2} \text{ )} \]

points on \( X_0 \). Let \( V_0 \) be this number; then from the Riemann–Hurwicz formula,

\[ g_0 = \frac{V_0}{2} - \frac{n}{2} + 1 = \frac{(n - 2)^2}{4} \quad \text{ (resp. } g_0 = \frac{V_0}{2} - \frac{n - 1}{2} + 1 = \frac{(n - 2)^2 - 1}{4} \text{ ).} \]

Observe that formula (1) for the genus \( g \) of the curve \( X \) can be recovered; indeed \( X \) is a double covering of the curve \( X_0 \) branched at the points where \( u \) has an odd pole or zero; this only occurs at the \( n \) points \( P_i \) and one extra point where \( n \) is odd. So

\[ g = 2g_0 + \left\lceil \frac{n - 1}{2} \right\rceil = \frac{n(n - 1)}{2} \nu - (n - 1) \quad \text{ for } \nu = 1. \]

We conclude that

\[ \dim \text{Prym} = g - g_0 = \frac{n(n - 2)}{4}, \quad n \text{ even}, \]

\[ = \frac{(n - 1)^2}{4}, \quad n \text{ odd}. \]

The statement about linearization follows at once from Theorem 1.
2. The Special Orbits (a), (b), (c) of I, Theorem 4.4 (geodesic Flow on Ellipsoids, Neumann Problem, etc ...)

The curves defined by \( \det(A - zI) = 0 \), where

- (a) \( A = \alpha h + \Lambda_{xy}, \alpha = \text{diag}(\alpha_1, \ldots, \alpha_n), \alpha_i \text{ all distinct}, \)
- (b) \( A = \alpha h^2 + hA_{xy} - \Gamma_{xx}, \)
- (c) \( A = \alpha h^2 + hA_{xy} + (\Delta_{xy} - \alpha) \)

are hyperelliptic of the form

- (a) \( h^2 = -(x^2 + y^2 - (x, y)^2) \prod_{i=1}^{n-2} (t - \sigma_i) a(t)^{-1} \) with \( t = zh^{-1}, \)
- (b) \( h^2 = - |x|^2 \prod_{i=1}^{n-1} (t - \mu_i) a(t)^{-1}, \)
- (c) \( h^2 - 1 = 2(x, y) \prod_{i=1}^{n-1} (t - \nu_i) a(t)^{-1} \)

of genera \( g = n - 2, n - 1 \) and \( n - 1 \), respectively. The function \( h \) has the property

\[
(h) = \sum_{i=1}^{n} Q_i - \sum_{i=1}^{n} P_i,
\]

where the distinct points \( P_i \) correspond to \( h = \infty, t = \alpha_i \). One assumes that for some \( 1 \leq i \leq n, x_iy_j - x_jy_i \neq 0 \) for all \( j \neq i \). The eigenvectors of \( Ah^{-2} \) in the limit \( h \to 0 \) are all distinct, because they are the eigenvectors of the matrix \( L \) considered in I, (4.54). For instance in the geodesic flow case, the eigenvectors are the components of the Chasles frame. Then from Theorem 1, the matrices of the form above parametrize a part or all of the Jacobi variety. We now show they parametrize a Zariski open set of the Jacobi variety using a dimension count. Consider

- (a) \( \mathcal{S} = \{ A \mid \alpha \text{ fixed, } |x| = 1, (x, y) = 0, \det(A - zI) = Q(x, h) \} \)

modulo the rotation

\[
x_i \to x_i \cos \theta - \frac{y_i}{|y|} \sin \theta,
\]
\[
y_i \to x_i \sin \theta + \frac{y_i}{|y|} \cos \theta.
\]

The variety has dimension \( (2n - 3) - (n - 1) = n - 2 \), the same as \( \text{Jac}(X) \).

- (b) \( \mathcal{S} = \{ A \mid \alpha \text{ fixed, } (x, y) = 0, \det(A - zI) = Q(x, h) \} \)

has dimension \( (2n - 1) - n = n - 1 = \dim \text{Jac}(X) \).

- (c) \( \mathcal{S} = \{ A \mid \alpha \text{ fixed, } |x| = 1, \det(A - zI) = Q(x, h) \} \)

has dimension \( 2n - 1 - n = n - 1 = \dim \text{Jac}(X) \).

\[ \Delta_{xy} = x \otimes y - y \otimes x, \Gamma_{xx} = x \otimes x, \Delta_{yy} = x \otimes y + y \otimes x. \]

\[ \text{The isospectral set is obtained by dividing out by the discrete action } (x_i, y_i) \to (-x_i, -y_i). \]
Finally the linearization of the flows described in I, Section 4, is straightforward by Theorem 1.

3. The Lagrange Top

It describes the motion of a rigid symmetric body \((I_1 = I_2)\) under gravity, with center of gravity belonging to the principal axis. As was explained in I, Sections 2 and 4, the equations of motion take the form

\[
\frac{d}{dt} (\gamma + hM + h^2 l, \Omega + lh) = [\gamma + hM + h^2 l, \Omega + lh],
\]  

(4)

where

\[
\gamma = \begin{pmatrix} 0 & -\gamma_3 & \gamma_2 \\ \gamma_3 & 0 & -\gamma_1 \\ -\gamma_2 & \gamma_1 & 0 \end{pmatrix}, \quad M = \begin{pmatrix} 0 & -I_3\Omega_3 & I_2\Omega_2 \\ I_3\Omega_3 & 0 & -I_1\Omega_1 \\ -I_2\Omega_2 & I_1\Omega_1 & 0 \end{pmatrix}, \\
\Omega = \begin{pmatrix} 0 & -\Omega_3 & \Omega_2 \\ \Omega_3 & 0 & -\Omega_1 \\ -\Omega_2 & \Omega_1 & 0 \end{pmatrix}
\]

We perform a unitary operation on \(A' = \gamma + hM + R^2 l\) in order to make the leading coefficient \(I_1 l\) diagonal. Let

\[
U = \begin{pmatrix} 0 & i/2^{1/2} & 1/2^{1/2} \\ 0 & 1/2^{1/2} & i/2^{1/2} \\ 1 & 0 & 0 \end{pmatrix}.
\]

Then

\[
A = U^{-1}A'U
\]

\[
= \begin{pmatrix} 0 & -i 2^{1/2} (A_{13}' - iA_{23}') - 1/2^{1/2} (A_{13}' + iA_{23}') \\ -i 2^{1/2} (A_{13}' + iA_{23}') & -iA_{12}' & 0 \\ 1/2^{1/2} (A_{13}' - iA_{23}') & 0 & iA_{12}' \end{pmatrix} \]

\[
= \begin{pmatrix} 0 & \beta & i\beta^* \\ -\beta^* & -\omega & 0 \\ i\beta & 0 & \omega \end{pmatrix}
\]

\(^{17}\) See Ratiu and van Moerbeke [20] and especially Ratiu [19].
with
\[
\beta = -\frac{i}{2^{1/2}} (A'_1 - iA'_2) = y + hx, \quad \beta^* = \bar{y} + h\bar{x},
\]
\[
y = \frac{1}{2^{1/2}} (\gamma_1 - i\gamma_3), \quad x = \frac{I_1}{2^{1/2}} (\Omega_1 - i\Omega_3)
\]
and
\[
\omega = iA_{12} - i(-z_0I_1h^2 - I_3\Omega_3h - \gamma_3).
\]
Then the curve \(X\) is defined by
\[
Q(z, h) = \det(A - zI) = -z[z^2 - \omega^2 + 2\beta\beta^*] = 0,
\]
which amounts to the elliptic curve
\[
z^2 = P_4(h) = \omega^2 - 2\beta\beta^*
\]
with two points \(P\) and \(Q\) covering \(h = \infty\) and \(R_1\) and \(R_2\) covering \(h = 0\); so
\[
(h) = -P - Q + R_1 + R_2,
\]
\[
(z) = -2P - 2Q + 4\text{ other zeros}.
\]
The eigenvectors \(f = (f_1, f_2, f_3)\) normalized at \(f_1 = 1\) equal
\[
f_2 = \frac{A_{12}}{A_{11}} \beta^*(\omega - z) = \frac{\beta^*}{\omega^2 - z^2},
\]
\[
f_3 = \frac{A_{19}}{A_{11}} = \frac{i\beta(\omega + z)}{-(\omega^2 - z^2)} = -\frac{i\beta}{\omega - z} = \frac{\omega + z}{2i\beta^*};
\]
observe that \(f_2 \cdot f_3 = -i/2\). In view of (5) and the expansion
\[
z = \pm iy_0I_1h^2 \left(1 + \frac{I_3\Omega_3}{y_0I_1} \frac{1}{h} + O \left(\frac{1}{h^2}\right)\right) \text{ about } P \text{ and } Q,
\]
we have that
\[
\omega + z = O(1) \quad \text{at } P,
\]
\[
= -2iy_0I_1h^2 + O(h) \quad \text{at } Q
\]
so that
\[
(f_2)_{\infty} = -P + Q, \quad (f_3)_{\infty} = P - Q.
\]
According to (6), the function \(f_2\) has a pole at the point \(\nu\) defined by \(\omega + z = 0\) and \(\beta = 0\), i.e., \(h = -y/x\) and \(z = \omega \big|_{h=-y/x}\) and has a zero at the point \(\bar{\nu}\).
defined by $\omega - z = 0$ and $\beta^* = 0$, i.e., $h = -\overline{y}/x$ and $z = \omega \mid_{h = -y/z}$. Therefore,

$$(f_2) = -P + Q - \nu + \nu^*$$

and

$$(f_3) = P - Q + \nu - \nu^*.$$  

This defines a map $A_h \to \nu$ from

$$\mathcal{A}(X) = \{A_h \mid A_h \text{ of the form above, } z_0 \neq 0 \text{ and } \det(A_h - zI) = Q(z, h) \text{ mod the rotation } x \to xe^{i\theta} \text{ and } y \to ye^{i\theta}$$

to the curve $X$. To show that the map is onto, we show that it is one-to-one. From the curve one determines uniquely the coefficients of the polynomial $\omega^2 - 2\beta^*$ in $h$, in particular $z_0 I_1$ and $I_2 \Omega_3$. The divisor $\nu$ defines $-y/x$ and $\omega$ evaluated at $h = -y/x$; therefore, from (5),

$$\gamma_3 = i\omega - z_0 I_1 h^2 - I_2 \Omega_3 h \mid_{h = -y/z}$$

and also $\omega$, as a polynomial in $h$, are known. Hence the polynomial in $h$

$$x^2 - \omega^2 - 2\beta^* = -2(|y|^2 + |x|^2 h^2 + (y\overline{x} + \overline{y}x)h)$$

is known, i.e., $|y|^2$, $|x|^2$, $(y\overline{x} + \overline{y}x)$ and $\overline{xy} = (y/x) |x|^2$. This implies that $x$ and $y$ are known, up to a common rotation $x \to xe^{i\theta}, y \to ye^{i\theta}$.

The linearization statement can be established by direct computation or by the general method, somewhat adapted. The direct computation cannot be generalized to higher dimensions, while the general method could easily be extended to higher dimensions. Any linear flow of the point

$$v = (h, z)$$

on the elliptic curve $x^2 = \omega^2 - 2\beta^*$, reads

$$\dot{h} = \pm c\omega \mid_{h = -y/z} \pm cix = \pm (z_0 I_1 y^2 + I_2 \Omega_3 yx - \gamma_3)$$

$$x = (xy - \overline{y}x).$$

Since, from the differential equations (4)

$$\dot{x} = -i \left(\frac{I_3 - I_1}{I_1}\right) \Omega_3 x + i\gamma_3,$$

$$\dot{y} = i\Omega_3 y - \frac{i\gamma_3}{I_1} x,$$
we have that \( c = \pm I_1^{-1} \); hence, the Lagrange top motion is a linear flow on \( \text{Jac}(X) = X \).

We now apply the general method to this case. Consider the non-singular curve \( X_\epsilon \) of genus = 4 defined by

\[
Q_\epsilon(x, h) = \det(A^{(\epsilon)} - xI) = \det \begin{pmatrix}
\epsilon h^2 - z & \beta & i\beta^* \\
-\beta^* & -\omega - z & 0 \\
i\beta & 0 & \omega - z
\end{pmatrix}
\]

\[= (\epsilon h^2 - z)(x^2 - \omega^2) - 2\beta\beta^*z \]

\[= -z^3 + \epsilon h^2 z^2 + (-2\beta\beta^* + \omega^2)z - \epsilon h^2 \omega^2 = 0,
\]

with three points \( P_1, P_2, P_3 \) defined by \( z = \infty, h = \infty \) such that

\[
\frac{z}{h^2} \simeq a_1 = \epsilon \quad \text{at } P_1 \\
\simeq a_2 = -iz_0 I_1 \quad \text{at } P_2 \\
\simeq a_3 = iz_0 I_1 \quad \text{at } P_3
\]

where \( \epsilon \to 0 \), \( X_\epsilon \) tends to a reducible curve \( X_0 \) containing \( X \); the points \( P_2 \) and \( P_3 \) go over into \( P \) and \( Q \). The nonzero flow generated by the meromorphic function \( I_1^{-1}zh^{-1} \) linearizes, as a consequence of Theorem 1, on the four-dimensional variety \( \text{Jac}(X_\epsilon) \). The Lax point corresponding to this flow reads

\[
A_{\epsilon} = [A^{(\epsilon)}I_1^{-1}(A_1^{(\epsilon)} + A_2^{(\epsilon)}h)].
\]

When \( \epsilon \searrow 0 \), it converges to \( A = [A, \tilde{B}] \), where

\[
\tilde{B} = \begin{pmatrix}
0 & I_1^{-1}x & iI_1^{-1}x \\
-I_1^{-1}x & i\Omega_3^{-1}I_1 & 0 \\
iI_1^{-1}x & 0 & -i\Omega_3
\end{pmatrix} + \begin{pmatrix}
0 & 0 & 0 \\
0 & iz_0 & 0 \\
0 & 0 & -iz_0
\end{pmatrix} h
\]

and the linear flow on \( \text{Jac}(X_\epsilon) \) goes over into a linear flow on \( \text{Jac}(X_0) \) and, more specifically, on its compact piece \( \text{Jac}(X) \). Since the matrix \( A \) can always be conjugated by a diagonal matrix depending on \( t \), without modifying the flow on \( \text{Jac}(X_0) \), we may modify the diagonal entries of \( B \) so as to get

\[
B = \begin{pmatrix}
0 & I_1^{-1}x & iI_1^{-1}x \\
-I_1^{-1}x & i\Omega_3^{-1}I_1 & 0 \\
iI_1^{-1}x & 0 & -i\Omega_3
\end{pmatrix} + \begin{pmatrix}
0 & 0 & 0 \\
0 & iz_0 & 0 \\
0 & 0 & -iz_0
\end{pmatrix} h
\]

\[= U^{-1}(\Omega + lh)U,
\]

which establishes the linearity of the original flow (4).
Remark. It is interesting to further explore some phenomena of Example 2. In the ellipsoidal problem (see, for instance, Arnold [24]) or the Neumann problem (see, for instance, Devaney [25]), one knows that one has hyperbolic phenomena. Associated to geodesic motion on the ellipsoid

\[ \frac{x_1^2}{a} + \frac{x_2^2}{b} + \frac{x_3^2}{c} = 1, \quad a < b < c, \]

we have a curve of the form \( X: h^2 = z(x - \mu_1)/(x - a)(x - b)(x - c) \), but the hyperbolic periodic orbit \( U \) about \( x_2 = 0 \), corresponds to the case \( \mu_1 = b \), and it linearizes on the real part of the Jacobian of the curve \( h^2 = z/(x - a)(x - c) \).

Orbits entering the stable manifold of \( U \) wind into \( U \) as time \( t \to \infty \), while these orbits actually hook up to the unstable orbit as \( t \to -\infty \), and hence wind backwards into \( U \). These orbits in fact are characterized as those passing through the umbilics of the ellipsoid (see Arnold [24]). Such asymptotically behaved orbits could not possibly be linearized on a torus and so must correspond to the case where the curve \( X \) is singular i.e. (see I, Section 2, for definition of the \( F_i \)'s)

\[ \frac{x^2}{(x - a)(x - b)(x - c)} = \frac{F_1(x, y)}{x - a} + \frac{F_2(x, y)}{x - b} + \frac{F_3(x, y)}{x - c} = \Phi, \]

From I, Section 2, and the above it follows that the stable–unstable manifold is the two-dimensional real variety \( V \) in \( R^6 \) given by

\[ V = \{(x, y) \mid \frac{F_1}{a} + \frac{F_2}{b} + \frac{F_3}{c} = 0, (b + c)F_1 + (a + c)F_2 + (a + b)F_3 = 0, |x| = 1, \langle x, y \rangle = 0\}. \]

Thus our isospectral set maps into the generalized Jacobian of \( X \), which is \( C \times \text{torus} \), whose real part is a cylinder. The geodesic flow corresponding to the stable–unstable variety \( V \) is linearized on a cylinder, with exponentials playing a role, as in fact is intuitively suggested by the asymptotic orbits “screwing” forward and backwards in time into the hyperbolic orbit \( U \). It would be interesting to explicitly show from our machinery that the coefficients of the exponentials are the Floquet multipliers, as they must be. A similar discussion applies to the Neumann problem, which may have equilibrium points\(^\text{18}\) (as none of the \( \mu_i \)'s need be zero) and thus as Devaney [25] discussed, the Neumann flow is far from ergodic near hyperbolic equilibria points. In general the linearizations will take place on \( \text{Real Jacobian}(X) = R^k \times T^j \) for appropriate \( j, k \), again with exponentials playing a role.

There is one technical hitch to this argument, namely the assumption that if the curve is nonsingular the flow is actually linearized on the torus, with no

\(^{18}\) This must be related to the \( n \)-soliton solution of the \( KdV \) equation using the well known relation between the \( KdV \) equation and the Neumann problem.
exceptional behavior. To see that, one must check that for this case, the map $\mathcal{A}(X) \mapsto \text{Jac}(X)$ is defined for all $A \in \mathcal{A}(X)$. For the case $n = 3$, geodesic flow, it is easy to see that the criteria of Theorem 1 are satisfied, for if there is one zero element in every row, then we might as well assume the first row and column of $A_1 = A_{n-1} = A_{xy}$ to be zero. In that case, it is easy to see, since $|x| \neq 0$, that either $x_i = y_i = 0$ for some $i$, in which case we are in the $n = 2$ (periodic orbit) case, or else $A_{xy} = 0$. In that case by the formula $X: h^2 = z(z - \mu_1)/(z - a)(z - b)(z - c)$, at most one of the $x_i$ may equal zero, in which case we are again in the $n = 2$ case. If none of the $x_i$ equal zero, by the equations of motion (I, Theorem 4.4) for geodesic flow, we see that $A_{xy}$ instantly has all non-zero entries, and so we can use the flow to complete the map $\mathcal{A}(X) \mapsto \text{Jac}(X)$, for these special cases. Thus the hypotheses of Theorem 1 are verified and so asymptotic geodesic flow is linearized on a cylinder. This argument fails for $n > 3$, but nonetheless singular curves and hence asymptotic behavior associated with the joining of the stable and unstable manifold abound. We just cannot rigorously prove there is a one-to-one relation, although it is undoubtedly true.

4. INDEPENDENCE OF THE LINEARIZATION ON THE REPRESENTATION

We have seen in Sections 2 and 3 how to linearize the various differential equations of this paper. We noted that the linearization takes place on the Jacobian of the curve $X$ defined by the Kac–Moody recipe. Moreover it was noted in I, Section 3, that the curve $X$ is representation dependent. The recipe for linearization, although given for the classical representation (minimal dimensional), extends to the higher-dimensional representations. Since the ordinary differential equations and their isospectral sets are representation independent, one would expect that the Jacobians of the curves associated with the different representations have a common abelian subvariety on which the linearization takes place. This is in fact the case; the purpose of this section is to prove this fact.

Consider the hyperelliptic curve

$$F(z, t) = A(t + t^{-1}) + P(z) = \prod_{1}^{N} (z - \lambda_i(t)) = 0,$$

where $A$ is a non-zero number and $P(z)$ an arbitrary monic polynomial of degree $N$. Fix $1 \leq \tau \leq N$; let $\alpha_i$ ($1 \leq i \leq \tau$) be integers and let $l_i(j_1, \ldots, j_n) = j_i$. Suppose

$$\alpha_1 = \ldots = \alpha_{a_1}, \alpha_{a_1+1} = \ldots = \alpha_{a_1+a_2}, \ldots, \alpha_{a_1+\ldots+a_{l-1}+1} = \ldots = \alpha_{a_1+\ldots+a_l}$$

with $\sum_{i} a_i = \tau$. Let $\pi$ denote a permutation of the set $(1, \ldots, N)$. 
Consider now the curve $X'$, defined by

$$G(x, t) \equiv \prod \left( x - \sum_{i=1}^{\tau} \alpha_i \lambda_{i(t)}(t) \right) = 0,$$

where the product extends over the orbit of $\sum_{i=1}^{\tau} \alpha_i \lambda_{i}(t)$ under the action of the permutation group $\{\pi\}$. $X'$ will be irreducible with $X$, by I, Lemma 3.1; the latter is generically irreducible. Observe that the curves associated with any higher-order representation involve curves of the type $X'$ in the case of the Toda systems. This section is concerned with proving the following theorem.

**Theorem 1.** When $X$ is non-singular, the following decomposition holds:

$$\text{Jac}(X') = \text{Jac}(X) \oplus B,$$

where $B$ is an abelian variety and where $\oplus$ is understood to be a direct sum modulo a finite group of translations (isogenies) and therefore, whatever be the representation the linearization can always take place on the $\text{Jac}(X)$ piece of the $\text{Jac}(X')$, and hence the linearization is indeed representation independent.

**Remark.** The above theorem deals with the Toda system of $sl(n)$, but can be extended to the other classical groups; this point will be discussed at the end.

**Proof of the theorem.** $X$ is an $N$-sheeted covering of the $t$-plane, while $X'$ is an $M'$-sheeted covering with

$$M' = \frac{N!}{a_1! \cdots a_\tau! (N - \tau)!}.$$

For notation, definitions and theorems about correspondences, the reader is referred to the Appendix. Consider now the correspondence $C[n, n']$ between $X$ and $X'$ defined by

$$(t, \lambda_m(t)) \rightarrow \left\{ \left( t, \sum_{i=1}^{\tau} \alpha_i \lambda_{i(t)}(t) \right) \middle| \text{ over all permutations } \pi \text{ such that } l_i(\pi) = m \text{ for some } i \right\}$$

and the inverse correspondence between $X'$ and $X$ defined by

$$\left( t, \sum_{i=1}^{\tau} \alpha_i \lambda_{i(t)}(t) \right) \rightarrow \{ (t, \lambda_{i(t)}(t)) \ | \ 1 \leq i \leq \tau \}.$$

This is indeed a correspondence; the two equations can be exhibited.\footnote{They take a particularly simple form when $G(x, t) = \Pi_{i \neq j} (x - (l_i + l_j))$; to wit, $F(x, t) = 0, t = t', F(x' - x, t) = 0, G(x', t') = 0$. In the general case, the expressions are more complicated.}
The indices of the correspondence are \( n = \tau \) and

\[
n' = \sum_{m=1}^{\tau} \frac{(N - 1)!}{a_1! \cdots (a_{m-1}! a_{m+1}! \cdots a_{m}! (N - \tau)!} = \frac{M'}{N} \sum_{m=1}^{\tau} a_m = M' \frac{\tau}{N} (3)
\]

because the number of elements in the orbit above containing a fixed element \( \lambda_i \) can be obtained by adding \( \alpha_{a_1 + \cdots + a_m \lambda_i} \) to each of the permutations of \( \lambda_1, \ldots, \lambda_{i-1}, \lambda_{i+1}, \ldots, \lambda_N \), where \( m \) ranges between 1 and \( \tau \). We now state two lemmas, whose proofs will be delayed.

**Lemma 1.** The correspondence \( C[n, n'] \) between \( X \) and \( X' \) is singular.

**Lemma 2.** Generically \( \text{Jac}(X) \) is irreducible, i.e., \( \text{Jac}(X) \) has no nontrivial subabelian varieties.

Let \( R \) be the homomorphism between \( \text{Jac}(X) \) and \( \text{Jac}(X') \) induced by the correspondence \( C[n, n'] \) between \( X \) and \( X' \). Fix a generic curve \( X \), for which \( X \) is nonsingular and irreducible. By Lemma 1, this homomorphism is nontrivial. Then, according to Weil [22, p. 22, Theorem 112], there is an abelian subvariety

\[
A \subset \text{Jac}(X)
\]

and a finite number of points \( a_i \in \text{Jac}(X) \), forming a group such that

\[
\ker h = \bigcup_i (A + a_i).
\]

But since \( \text{Jac}(X) \) is irreducible, \( \ker h \) is a finite group; so \( h(\text{Jac}(X)) \) can be regarded as a subabelian variety \( A' \) of \( \text{Jac}(X') \), modulo the finite group accounting for isogenies. By the "Poincaré reducibility theorem" (Weil [22, p. 176, Theorem 26]), there is another abelian variety \( B' \subset \text{Jac}(X') \) such that

\[
A' \cap B' = \text{finite subgroup of } \text{Jac}(X'),
\]

\[
\forall x \in \text{Jac}(X'), x = y + z \quad \text{with} \quad y \in A', z \in B'.
\]

Observe that the decomposition above is not unique; if \( x = y + z = y' + z' \), then \( y - y' = z' - z \in A' \cap B' \), which is a finite set. Therefore the decomposition can be chosen in a consistent fashion so that

\[
\text{Jac}(X') = A' \oplus B',
\]

\( A' \) is isogenic to \( \text{Jac}(X) \).
For the nonsingular curves $X$ for which $\text{Jac}(X)$ is reducible, one uses a different argument, invoking the principle of specialization, to be explained below. Consider the coefficient of $P(z)$ in the expression $F(z, t)$ to be the indeterminates $u_1, \ldots, u_N$, which take on values in $U = \mathbb{C}^N \setminus \{\text{points where } X \text{ becomes singular}\}$. If $u = (u_1, \ldots, u_N)$ is specialized to $u^0 = (u_1^0, \ldots, u_N^0) \in U$, the curve $X_u$ specializes to $X_{u^0}$. With Chow [4] and Matsusaka [12] construct the Jacobi variety $\text{Jac}(X_u)$ (thought of as defined over the indeterminates $u_1, \ldots, u_N$); it has the property that

\[
\text{Jac}(X_u)|_{u = u_0} = \text{Jac}(X_{u_0}).
\]

Similarly, the equation $G(z, t) = 0$ is a polynomial in the indeterminates $u_1, \ldots, u_N$ and the equation defining the correspondence between $X_u$ and $X'_{u'}$ as well. Let $\Gamma_u$ be the graph of the associated homomorphism $h_u$ between $\text{Jac}(X_u)$ and $\text{Jac}(X'_{u'})$:

\[
\Gamma_u \subset \text{Jac}(X_u) \times \text{Jac}(X'_{u'});
\]

$\Gamma_u$ is an algebraic subvariety; since $h_u$ is a homomorphism, $\Gamma_u$ has the group structure induced by $\text{Jac}(X_u) \times \text{Jac}(X'_{u'})$. Therefore, according to [4] and [12] $\Gamma_u$ is a subabelian variety over the field generated by $u_1, \ldots, u_N$. By putting $u = u_0$, $\Gamma_{u_0}$ is a closed algebraic subset of $\text{Jac}(X_{u_0}) \times \text{Jac}(X'_{u_0})$, which is also a group. Therefore by

\[
\Gamma_u |_{u = u_0} = \Gamma_{u_0}.
\]

Also

\[
\text{proj}_{\text{Jac}(X'_{u'})} \Gamma_u = A_u
\]

has the same dimension as $\Gamma_u$. Under the theorem of specialization (Matsusaka [13] or Shimura [21])

\[
A_u |_{u = u_0} = A_{u_0}
\]

and in the specialization the dimension does not drop; so therefore $\dim h_{u_0}(\text{Jac } X_{u_0}) = \dim A_{u_0} = \dim A_u = \text{the dimension of } \{\text{the generic } A_{u_1} \text{ for } u_1 \in U\} = g$ and the result that $\text{Jac}(X)$ is a subabelian variety of $\text{Jac}(X')$ holds even for a nonsingular $X$, for which $\text{Jac}(X)$ is reducible. This establishes Theorem 1.

We now prove Lemmas 1 and 2:

Proof of Lemma 1. Theorem 1 of the Appendix will be used to show that the correspondence between $X$ and $X'$ is nonsingular; it will suffice to show that

\[
\eta < 2n(n' + g' - 1),
\]
where \( n = \tau, n' = M'/N \) and \( g' \) is the genus of curve \( X' \). We have mentioned that the correspondence \( C[n, n'] \) was given by two equations; this does not suffice to conclude nonsingularity of \( C \), because possibly these two equations could be reduced to one in the usual or in some other coordinates. Therefore we establish the inequality above. Unfortunately \( \eta \) cannot be computed by inspection, because most coincidence points \( p \in X \) (where \( C(p) \) has at least double points) are all branch points of \( X \) with regard to the \( t \)-plane; also for these points, \( C(p) \) contains branch points of \( X' \), which makes it a delicate matter. Instead of this argument, we use Zeuthen's formula (Lemma 1 of the Appendix) to compute \( \eta \).

Introduce the graph curve \( X'' \) of the correspondence \( C[n, n'] \), whose sheet number equals \( n'N \). Let \( g'' \) be its genus. There is a \( C[l, n'] \) correspondence between \( X \) and \( X'' \); hence, according to Lemma 2 (Zeuthen formula) of the Appendix:

\[
\eta = 2(g'' - 1) - 2n'(g - 1).
\]

So, it suffices to show that

\[
(g'' - 1) - n'(g - 1) - \tau(g' - 1) \leq n'.
\] (4)

Let \( V, V' \) and \( V'' \) denote the ramification indices of \( X, X' \) and \( X'' \) respectively. Then according to the Riemann Hurwicz formula,

\[
g'' - 1 = \frac{V''}{2} - n'N,
\]

\[
g - 1 = \frac{V}{2} - N,
\]

\[
g' - 1 = \frac{V'}{2} - M'.
\]

Combining the relations (3) and (4), it suffices to show that

\[
\frac{V''}{2} - n' \frac{V}{2} - \tau \frac{V'}{2} < -(N - \tau)n'.
\] (5)

Generically, \( X \) has \( 2(N - 1) \) simple branch points for \( t \in \mathbb{C}^* \) and a branch point of index \( N - 1 \) at \( t = 0 \) and at \( t = \infty \), so that

\[
V = 4(N - 1).
\]

The curve \( X' \) will have branch points for those values of \( t \in \mathbb{C}^* \) which produce branch points for \( X \), at \( t = 0 \) and at \( t = \infty \). Whenever \( \lambda_i = \lambda_j \), one has two types of branch points. First obtained by adjoining \( \lambda_i \) or \( \lambda_j \) to all the different
combinations of $\tau - 1$ symbols (taken from the $N - 2$ symbols $\lambda_1, \ldots, \lambda_j, \ldots, \lambda_n$) in the “box” corresponding to $a_m$ over all $m$ ($1 \leq m \leq l$)

$$\sum_{m=1}^{l} \frac{(N-2)!}{a_1! \cdots! (a_m-1)! \cdots! a_1! (N-\tau-1)!} = \frac{(N-\tau)}{(N-1)^{n'}}.$$ 

Second, those obtained by adjoining $\lambda_i$ and $\lambda_j$ to all the different combinations of $\tau - 2$ symbols (taken from the $N - 2$ symbols $\lambda_1, \ldots, \lambda_i, \ldots, \lambda_j, \ldots, \lambda_N$) in the “boxes” corresponding to $a_m$ and $a_{m'}$ with $m \neq m'$:

$$\sum_{m \neq m'} \frac{(N-2)!}{a_1! \cdots! (a_m-1)! \cdots! (a_{m'}-1)! \cdots! a_1! (N-\tau)!} - \frac{n'}{\tau(N-1)} \sum_{m \neq m'} a_m a_{m'}$$

$$\quad = \frac{n'}{\tau(N-1)} \left( \frac{\tau^2}{2} - \sum_{i=1}^{l} \frac{a_i^2}{2} \right)$$

Assume that the roots $\lambda_1 \cdots \lambda_N$ of $F$ (see (1)) are labeled such that winding once around $t = 0$ or $t = \infty$ amounts to going from sheet $\lambda_i$ to sheet $\lambda_{i+1}$. This transformation $i \rightarrow i + 1$ extends to

$$\sum_{i=1}^{\tau} \alpha_i \lambda_{i+1} \rightarrow \sum_{i=1}^{\tau} \alpha_i \lambda_{i+1} \quad \text{with} \quad \lambda_{N+1} = \lambda_1.$$ 

Let $r_k$ be the number of elements in each orbit under this transformation, where $1 \leq k \leq \# \text{ orbits}$. Then the ramification index at $t = 0$ and $t = \infty$ combined equals

$$2 \sum_{1 \leq k \leq \# \text{ orbits}} (r_k - 1) = 2M' - 2 \# \text{ orbits}.$$ 

Therefore we conclude that, using (3), i.e., $n' = M'/N$,

$$\frac{\tau V'}{2} = 2(N-1)\frac{\tau}{2} \left[ \frac{N-\tau}{N-1} n' + \left( \frac{\tau^2}{2} - \sum_{i=1}^{l} \frac{a_i^2}{2} \right) \frac{1}{\tau(N-1)} n' \right]$$

$$+ \frac{1}{2} (2\tau M' - 2\tau \# \text{ orbits})$$

$$= \tau(N-\tau)n' + \left( \frac{\tau^2}{2} - \sum_{i=1}^{l} \frac{a_i^2}{2} \right) n' + n'N - \tau \# \text{ orbits}.$$ 

The points of the graph curve are given by

$$\left( \lambda_i(t), \sum_{k=1}^{\tau} \alpha_i \lambda_k(t) \right) \text{ over all } i \text{ and all }$$

$$\text{permutations such that } \lambda_{i_k} = \lambda_i \text{ for some } k \right\}$$
over the $t$-plane. For those $t \in \mathbb{C}^*$ for which $\lambda_i(t) = \lambda_j(t)$, branch points occur in three different fashions.

(i) Every point of the type $(\lambda_i(t), \sum_{k \neq i}^r \alpha_k \lambda_k(t))$ equals some point of the type $(\lambda_j(t), \sum_{k \neq j}^r \alpha_k \lambda_k(t))$ and vice versa; so taking into account all the affine branch points of $X$ this contributes

$$2n'(N - 1)$$

to the ramification index.

(ii) Within the group of points $(\lambda_h(t), \sum_{k \neq h}^r \alpha_k \lambda_k(t))$, $h \neq i, j$, there are some points containing $\lambda_i$ and not $\lambda_j$ and some $\lambda_j$ and not $\lambda_i$. Whenever $\lambda_i = \lambda_j$, some point in the first group equals a corresponding point in the second group and vice versa. Its number equals the number of different combinations $\sum_{k \neq h}^r \alpha_k \lambda_k(t)$ containing $\lambda_h$ and $\lambda_i$ and not $\lambda_j$ for fixed $h$, i.e.,

$$\sum_{s,t} \frac{(N - 3)!}{(N - \tau)(N - 1)(N - 2)} a_1 \cdots a_t (a_s - 1)! \cdots (a_u - 1)! \cdots a_t (N - \tau - 1)!$$

$$= \frac{(N - 3)!}{(N - \tau)(N - 1)(N - 2)} n' \left( \sum_{s \neq t}^r a_s a_t + \sum_s^r a_s(a_s - 1) \right)$$

$$= \frac{(N - \tau)(N - 1)}{(N - 1)(N - 2)} n'.\)

Let now $t \in \mathbb{C}^*$ run over all branch points of $X$ and let $h \neq i, j$ run from 1 to $N$; then the total contribution amounts to

$$2(N - 1)(N - 2) \frac{(N - \tau)(N - 1)}{(N - 1)(N - 2)} n' = 2(N - \tau)(N - 1)n'.\)

(iii) Within the group of points $(\lambda_h(t) \sum_{k \neq h}^r \alpha_k \lambda_k(t))$, $h \neq i, j$, there are some points containing $\lambda_i$ and $\lambda_j$ in different “boxes.” For a given such group, permuting $\lambda_i$ and $\lambda_j$ leads to a different combination; but, when $\lambda_i = \lambda_j$, they are the same. The number of such combinations is given by the different combinations $\sum_{k \neq h}^r \alpha_k \lambda_k(t)$ containing $\lambda_h$ and $\lambda_i, \lambda_j$ in different boxes. Its number equals

$$\sum_{t \leq u \atop \text{all } s} \frac{(N - 3)!}{(a_1 - 1)! \cdots (a_s - 1)! \cdots (a_u - 1)! \cdots a_t (N - \tau)!}.\)

When $h$ takes on all values $\neq i, j$ and $t \in \mathbb{C}^*$ runs over all the branch points of $X$, the total number of such points equals
Finally, both at $t = 0$ and $t = \infty$, there are $n'$ branch points each of index $N - 1$, because winding around $t = 0$ or $t = \infty$ has the effect of raising each of the $n'$ sheets associated to $\lambda_i$ into each of the $n'$ sheets associated to $\lambda_{i+1}$ in $X''$; this contributes

$$2n'(N - 1)$$

to the ramification index. Adding up these contributions,

$$\frac{V''}{2} = 2n'(N - 1) + (N - \tau)(\tau - 1)n' + n' \left( \frac{\tau^2}{2} - \sum \frac{a_s^2}{2} \right) - \frac{n'}{\tau} \left( \tau^2 - \sum a_s^2 \right).$$

Putting these expressions for $V$, $V'$ and $V''$ into the equality (5), we are led to the inequality

$$\# \text{ orbits} < \frac{n'N}{\tau} + \frac{n'}{\tau^2} \left( \tau^2 - \sum a_s^2 \right) = M' + \frac{n'}{\tau^2} \left( \tau^2 - \sum a_s^2 \right);$$

this inequality now is obvious, since the number of orbits is clearly smaller than $M'$. Note that whenever $\tau = a_1$ ($l = 1$), the right-hand side equals $M'$. This finishes the proof of Lemma 1.

Remark. The reader will observe that in the above, there is actually another source of ramification, namely, the case, for instance, where for a fixed $t = t_0$, $\lambda_1 + 3\lambda_6 = \lambda_2 + 3\lambda_8$, $\lambda_1 \neq \lambda_3$, $\lambda_6 \neq \lambda_8$. This leads to ramification on $X'$, $X''$, but not on $X$, and as we will show, such a situation leads to an increase $\delta V'$, $\delta V''$. 

in $V', V''$, such that $\delta V'' - \tau \delta V' \leq 0$, and so by (5), can be ignored in our computations. Suppose a sum consisting of $b_i \leq a_i$ of $\lambda_i$'s from each of the "boxes" of $a_i$ elements is equal to another such set, with entirely different $\lambda_i$'s. Set $\sum b_i = \tau' \leq \tau$. This leads to ramification on $X'$ by holding fixed in their "boxes," the first set of $\tau'$ $\lambda_i$'s, and considering how many points can occur over $t_0$, where the rest of the $\lambda_i$'s in the sum $\sum \alpha_i \lambda_{i(a)}(t_0)$ are drawn from the $N - 2\tau' \lambda_i$'s in neither of the two sets. Such points are coincident with the sum $\sum \alpha_i \lambda_{i(\alpha)}$, where the role of the first two sets of $\tau'$ points are interchanged. This clearly leads to $\delta V' = ((N - 2\tau')/\prod (a_i - b_i)! (N - \tau + \tau')!)$. On the $X''$ curve, the above situation leads to ramification at the points $(\lambda_i(t_0), \sum \alpha_n \lambda_{i_n}(t_0))$, where $\lambda_i(t_0)$ is not one of the $2\tau'$ points in the two special sets of $\lambda_i$, and the $\sum \alpha_n \lambda_{i_n}(t_0)$ contains $\lambda_i$ and one of the special sets, but no element in the other, and vice versa. This situation occurs precisely

$$\delta V'' = (N - 2\tau') \times \left( \sum_i (N - 2\tau' - 1)! / \prod_{j \neq i} (a_i - b_j)! (a_i - b_i - 1)! (N - \tau + \tau')! \right)$$

$$= \delta V'(\tau - \tau') \text{ number of times;}$$

hence $\delta V'' - \tau \delta V' = -\tau' \delta V' \leq 0$, as promised. That the above situation does not occur twice at the same time can be assumed by taking a generic $X$.

**Proof of Lemma 2.** The proof of this lemma is reminiscent of a proof of Lefschetz [8] for general curves, which cannot be applied to this case. Consider a real Toda curve $X$ with branch points $\lambda_1 < \lambda_2 < \cdots < \lambda_{2g+1}$ with homology cycles

$$c_j = a_j, \quad 1 \leq j \leq g,$$
$$= b_{j-g}, \quad g + 1 \leq j \leq 2g,$$

![Figure 1](image-url)
as in Fig. 1. Define $c_f(\omega) = \int e_f \omega$. The Toda character is expressed by the fact that (see Moerbeke [14])

$$
\sum_{i=1}^{g} m_i a_i(\omega_k) = N \int_{\gamma}^{\omega_k}, \quad 1 \leq k \leq g, 1 \leq m_1 < m_2 < \cdots < m_g < N,
$$
or, equivalently,

$$
\sum_{i=1}^{g} m_i \int_{\lambda_{2i-1}}^{\lambda_{2i}} \omega_k = N \int_{\lambda_{2j+1}}^{\lambda_{2j}} \omega_k, \quad 1 \leq k \leq g,
$$

$q$ real $< \infty$, different from branch points. (6)

As explained in McKean and Moerbeke [10], the Marcenko–Ostrovskii transformation maps the $\lambda$-plane of Fig. 1 cut along $[\lambda_1, \infty)$ to a slit domain with vertical spikes at the points $\pi m_i$ ($1 \leq i \leq g$). Conversely, any slit domain with vertical spikes at $g$ positive multiples of $\pi$ gets mapped into the $\lambda$-plane depicted in Fig. 1. The height of the $i$th spike controls the width of the corresponding band $[\lambda_{2i-1}, \lambda_{2i}]$ and since the height of the spikes can be chosen arbitrarily, the width of the bands can be varied independently of each other. So, in particular, any band can be squeezed to a point, while maintaining the other bands open, possibly at the expense of moving all the $\lambda_i$'s. This degree of freedom in the Toda variety is the main ingredient of the proof, reminiscent of an argument by Lefschetz [8].

Next we show that the Toda character of $X$ is maintained after squeezing one band; namely, it reduces to the Toda relation for the smooth Riemann surface $X_0$ of one lower genus. Indeed, let $\omega$ be an arbitrary differential vanishing at $z_j \in [\lambda_{2j-1}, \lambda_{2j}]$; then, when $\lambda_{2j} - \lambda_{2j-1} \rightarrow 0$,

$$
\omega = \frac{P(z)(z - z_j)}{(R(z))^{1/2}} \rightarrow \omega^0 = \frac{P(z)}{(R_0(z))^{1/2}}, \quad \text{degree} \ P(z) \leq g - 1,
$$

where $y^2 = R(z) \equiv (z - \lambda_0) \cdots (z - \lambda_{2g+1})$ and

$$
y_0^2 = R_0(z) \equiv (z - \lambda_0) \cdots (z - \lambda_{2g+1})(z - \lambda_{2j-1})(z - \lambda_{2j}) \cdots (z - \lambda_{2g+1}).
$$

So, $\omega$ tends to a generic holomorphic differential $\omega^0$ on the curve $X_0$ defined by $y_0^2 = R_0(z)$. Moreover

$$
\int_{\lambda_{2j-1}}^{\lambda_{2j}} \omega \rightarrow \int_{\lambda_{2j-1}}^{\lambda_{2j}} \omega^0, \quad i \neq j,
$$

and

$$
\int_{a}^{b} \frac{dz}{((x - a)(b - z))^{1/2}} = \pi \quad \text{and} \quad \int_{a}^{b} \frac{(z - c)dz}{((x - a)(b - z))^{1/2}} = \left(\frac{a + b}{2} - c\right)\pi,
$$

$a < c < b$. Using the integrals

$$
\int_{a}^{b} \frac{dz}{((x - a)(b - z))^{1/2}} = \pi \quad \text{and} \quad \int_{a}^{b} \frac{(z - c)dz}{((x - a)(b - z))^{1/2}} = \left(\frac{a + b}{2} - c\right)\pi,
$$

$a < c < b$.
\[
\int_{\lambda_{s_{j-1}}}^{\lambda_{s_j}} \omega = \int_{\lambda_{s_{j-1}}}^{\lambda_{s_j}} \frac{(x - z_j)}{((x - \lambda_{s_{j-1}})(x - \lambda_{s_j}))^{1/2}} P(z) \, dx \frac{(x - \lambda_i)^{1/2}}{\prod_{i \neq s_{j-1}, s_{j}} ((x - \lambda_i))^{1/2}}
\]
\[
= C \left(2 \frac{\lambda_{s_{j-1}} + \lambda_{s_j}}{2} - x_j\right) \pi \to 0.
\]

Therefore (6) reduces to

\[
\sum_{i=1}^{q} m_i \int_{\lambda_{s_{i-1}}}^{\lambda_{s_i}} \omega_k \omega = N \int_{\lambda_{s_{q+1}}}^{\lambda_{s_q}} \omega_k \omega
\]

which expresses the fact that \(X_0\) is also Toda.

For future use, we also evaluate \(b_j(\omega)\) for \(\omega\) vanishing or nonvanishing at \(z_j\) where \(\lambda_{s_j} = \lambda_{s_{j-1}} \to 0\). When \(\omega(z_j) \neq 0\), one gets after a deformation of the integration path.

\[
b_j(\omega) \sim C + C' \int_{\lambda_{s_{j-1}}}^{\lambda_{s_j}} \frac{dx}{((x - \lambda_{s_{j-1}})(x - \lambda_{s_j}))^{1/2}}
\]
\[
= \ln\left(2((\lambda_{s_{j-1}} - z)(\lambda_{s_j} - z))^{1/2} + 2\lambda_{s_{j-1}} - \lambda_{s_j} - \lambda_{s_{j-1}}\right) \bigg|_{\lambda_{s_{j-1}}}^{\lambda_{s_j}}
\]
\[
= \ln\left(\frac{\lambda_{s_{j-1}} - \lambda_{s_j}}{2(\lambda_{s_{j-1}} - \lambda_{s_j} + a))^{1/2} + \lambda_{s_{j-1}} - \lambda_{s_j} - 2a} \right)
\]
\[
= -O(\ln(\lambda_{s_{j-1}} - \lambda_{s_j})) \uparrow \infty \quad \text{logarithmically,}
\]

where \(C\) and \(C'\) are functions of the other branch points and \(a > 0\) is bounded away from zero. Moreover when \(\omega(z_j) = 0\),

\[
|b_j(\omega)| \sim C + C' \int_{\lambda_{s_{j-1}}}^{\lambda_{s_j}} \frac{(x - z_j) \, dx}{((x - \lambda_{s_{j-1}})(x - \lambda_{s_j}))^{1/2}}
\]
\[
\sim C + C' \left(\frac{\lambda_{s_{j-1}} + \lambda_{s_j}}{2} - x_j\right) O(\ln(\lambda_{s_{j-1}} - \lambda_{s_{j-1}})) < \infty.
\]

Assume now that every Toda curve is reducible; then, the period matrix \(\Omega = (c_i(\omega_i))\), 1 \(\leq i \leq g\), 1 \(\leq j \leq 2g\), splits up in two blocks (for a proper choice of cycles and basis \(\omega_i\) of holomorphic differentials), consisting of \(\Omega_1\), a matrix of order \((k, 2k)\), and \(\Omega_2\), of order \((g - k, 2(g - k))\)

\[
\Omega = \begin{pmatrix} \Omega_1 & 0 \\ 0 & \Omega_2 \end{pmatrix}.
\]

Since \(\Omega_1\) and \(\Omega_2\) correspond to abelian subvarieties, we have that for some
antisymmetric integer matrices $J_1$ and $J_2$ of order $2k$ and $2(g - k)$, respectively,

$$\Omega_1 J_1 \Omega_1^T = 0 \quad \text{and} \quad \Omega_2 J_2 \Omega_2^T = 0$$

as a consequence of the Riemann bilinear relations. Therefore both relations,

$$\Omega \begin{pmatrix} J_1 & 0 \\ 0 & J_2 \end{pmatrix} \Omega^T = 0 \quad \text{and} \quad \Omega \begin{pmatrix} J_1 & 0 \\ 0 & -J_2 \end{pmatrix} \Omega^T = 0$$

are valid, i.e., $\Omega$ has a complex multiplication besides the usual Riemann bilinear relation. Now since the Toda curves of fixed genus corresponding to the same relatively prime set of integers $0 < m_1 < m_2 < \cdots < m_g < N$ form an analytic variety [11], and since there are only a denumerable number of complex multiplications, they all must share the same additional complex multiplication; let

$$\Omega \ d \Omega^T = 0$$

for an integral matrix $d$ of size $2g$. This implies the quadratic relation

$$\sum_{i,j} c_i(\omega_k) d_{ij} c_j(\omega_i) = 0, \quad 1 \leq l, k \leq g.$$ 

Hence, for any pair of holomorphic differentials $\omega$ and $\omega'$

$$\sum_{i,j} c_i(\omega) d_{ij} c_j(\omega') = 0. \quad (11)$$

This relation now holds for all Toda curves of a given genus with fixed integers. We now show by induction on the genus that the matrix $d$ reduces to the symplectic matrix

$$J = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}.$$ 

More precisely, if this property is true for genus $= g - 1$, then it holds for genus $g$. The quadratic relation (11) can be split up in its real and imaginary parts, which because of the reality of the branch points leads to the following two relations (A) and (B):

$$\sum_{i=1}^g b_i(\omega_1) \sum_{j=1}^g n_{ij} b_j(\omega_2) + \sum_{i=1}^g a_i(\omega_1) \sum_{j=1}^g m_{ij} a_j(\omega_2) = 0.$$ 

By successive choices of $\omega_1$ and $\omega_2$, the integers $n_{ij}$ and $m_{ij}$ will be shown to vanish.

(i) Squeeze the cycle $a_g$ to the point $z_g (\lambda_{g-1} < z_g < \lambda_g)$ and let $\omega_g(z_g), \omega_g(z_g) \neq 0$. Then by (9), $b_g(\omega_1) b_g(\omega_2)$ blows up faster than $b_j(\omega_1) b_g(\omega_2)$ and $b_g(\omega_1) b_j(\omega_2) \; (1 < j < g - 1)$ while all the remaining terms in (A) remain finite by (7) and (8). This implies $n_{gg} = 0.$
(ii) Squeeze both cycles \( a_i \) \((1 \leq i \leq g)\) and \( a_g \) to the points \( z_i \) \((\lambda_{2i-1} < z_i < \lambda_{2i})\) and \( z_g \) \((\lambda_{2g-1} < z_g < \lambda_{2g})\), respectively; let

\[
\omega_1(z_i) \neq 0, \quad \omega_1(z_g) = 0 \quad \text{and} \quad \omega_2(z_i) = 0, \quad \omega_2(z_g) \neq 0.
\]

Then by (7), (8), (9), and (10), only \( b_i(\omega_1) \) and \( b_g(\omega_2) \) blow up; so the leading term in (A) is \( n_{1,g} b_i(\omega_1) b_g(\omega_2) \) with the result that \( n_{1,g} = 0, 1 \leq i \leq g - 1 \).

(iii) The roles of \( \omega_1 \) and \( \omega_2 \) can be reversed, implying that also \( n_{g,i} = 0, 1 \leq i \leq g \).

(iv) Consider now two arbitrary differentials \( \omega_1 \) and \( \omega_2 \) both vanishing at \( z_g \) \((\lambda_{2g-1} < z_g < \lambda_{2g})\) and squeeze \( a_g \). Then, according to (7) and (8), \( a_i(\omega_1) \) and \( b_j(\omega_1) \) \((1 \leq j \leq g - 1, 1 \leq i \leq 2)\) lead to generic abelian integrals for a Toda curve of genus \( g - 1 \), as pointed out before, and

\[
a_g(\omega_1) \to 0 \quad \text{and} \quad a_g(\omega_2) \to 0.
\]

So, relation (A), taking into account (i)-(iii), goes over into a similar relation for a generic Toda curve (defined by \( m_1 < m_2 < \cdots < m_{g-1} < M \)) of genus \( g - 1 \). By assumption, this generic curve has no complex multiplication, so that

\[
n_{ij} = m_{ij} = 0, \quad 1 \leq i, j \leq g - 1.
\]

(v) All that is left in (A) is the sum

\[
\sum_{j=1}^{g-1} m_{ij} a_g(\omega_1) a_j(\omega_2) + \sum_{j=1}^{g} m_{ij} a_j(\omega_1) a_g(\omega_2) = 0. \tag{12}
\]

Choose \( \omega_1 \) and \( \omega_2 \) such that

\[
\omega_1(z_1) = \cdots = \omega_1(z_{i-1}) = \omega_1(z_{i+1}) = \cdots = \omega_1(z_g) = 0,
\]

hence

\[
\omega_1(z_i) \neq 0 \quad \text{and} \quad \omega_2(z_g) \neq 0;
\]

then by (7) and (8), upon squeezing all \( a_i \) \((1 \leq i \leq g)\), \( a_g(\omega_1) \to 0 \) \((1 \leq j \leq g, j \neq i)\), \( a_i(\omega_1) \to 0\), \( a_2(\omega_2) \) finite, and \( a_g(\omega_2) \to 0\); therefore in the limit the only surviving term in (12) is \( \lim m_{ij} a_i(\omega_1) a_j(\omega_2) = 0 \) with \( \lim a_i(\omega_1) a_j(\omega_2) \neq 0 \); hence \( m_{ij} = 0 \) \((1 \leq i \leq g)\) and by interchanging the roles of \( \omega_1 \) and \( \omega_2 \), also \( m_{ji} = 0, 1 \leq i \leq g \); hence (A) is seen to be zero.

\[
(B) \sum_{i=1}^{g} b_i(\omega_1) \sum_{i=1}^{g} n_{ij} a_i(\omega_2) + \sum_{i=1}^{g} a_i(\omega_1) \sum_{i=1}^{g} m_{ij} b_i(\omega_2) = 0.
\]
(i) Squeeze all $a_i$ $(1 \leq i \leq g)$ and choose $\omega_1$ and $\omega_2$ such that

$$\omega_1(z_1) = \omega_1(z_2) = \cdots = \omega_1(z_{g-1}) = 0, \quad \lambda_{2i-1} \leq z_i \leq \lambda_{2i},$$

$$\omega_2(z_1) = \omega_2(z_2) = \cdots = \omega_2(z_{j-1}) = \omega_2(z_{j+1}) = \cdots = \omega_2(z_g), \quad 1 \leq j \leq g - 1.$$ 

Then, by (7), (8), (9), and (10), and the fact that $\omega_1(z_g) \neq 0$ and $\omega_2(z_j) \neq 0$,

$$|b_i(\omega_1)| < \infty, \quad 1 \leq i \leq g - 1, \quad |b_j(\omega_1)| \not< \infty,$$

and

$$|b_i(\omega_2)| < \infty, \quad 1 \leq i \leq g, \quad i \neq j, \quad |b_j(\omega_2)| \not< \infty,$$

and

$$a_i(\omega_1) \to 0, \quad 1 \leq i \leq g - 1, \quad a_j(\omega_1) \not\to 0,$$

$$a_i(\omega_2) \to 0, \quad 1 \leq i \leq g, \quad i \neq j, \quad a_j(\omega_2) \not\to 0.$$

Then both $a_i(\omega_1) b_j(\omega_2), \quad 1 \leq i \leq g - 1, \quad i \neq j,$

and $a_j(\omega_1) b_j(\omega_2) \to 0$ by letting $\lambda_{2i} - \lambda_{2i-1} \to 0$ independently of $1 \leq i \leq g - 1$, using estimates (7), (8), (9), and (10). Consequently, the leading term of (B), namely,

$$n_{gj} b_j(\omega_1) a_j(\omega_2) + m_{gj} a_j(\omega_1) b_j(\omega_2),$$

must vanish. Since both $\lambda_{2g} - \lambda_{2g-1}$ and $\lambda_{2j} - \lambda_{2j-1}$ can be made to vanish independently, we conclude that $n_{gj} = m_{gj} = 0$ $(1 \leq j \leq g - 1)$.

(ii) By interchanging the roles of $\omega_1$ and $\omega_2$, also $n_{ij} = m_{ij} = 0, \quad 1 \leq j \leq g - 1.$

(iii) Squeeze $a_j$ and put $\omega_1 = \omega_2$, with $\omega_2(z_g) \neq 0$; then using (i) and (ii),

the leading term reads

$$n_{g0} b_0(\omega_1) a_0(\omega_1) + m_{g0} a_0(\omega_1) b_0(\omega_1) = (n_{g0} + m_{g0}) a_0(\omega_1) b_0(\omega_1)$$

and it vanishes only if $n_{g0} = -m_{g0}.$

(iv) Consider now two arbitrary differentials $\omega_1$ and $\omega_2$ both vanishing at $z_g$. Then if $a_0$ gets squeezed, $a_i(\omega_i)$ and $b_i(\omega_i) \quad (1 \leq j \leq g - 1, \quad i = 1, 2)$ lead to generic abelian integrals for a Toda curve of genus $g - 1$, while $a_0(\omega_1) \to 0 \quad (i = 1, 2)$ by (8) and $b_0(\omega_1) \not< \infty \quad (i = 1, 2)$ by (10). Therefore in that limit, relation (B) tends to a complex multiplication for a generic Toda curve of lower genus, defined by $m_1 < m_2 < \cdots < m_{g-1} < N$. Since, by assumption, such a generic Toda curve has no complex multiplication, the limiting relation must reduce to Riemann's bilinear relation. Putting the corresponding values of $n_{ij}$ and $m_{ij}$ in relation (B) and taking into account (i)-(iii), we find for $c = n_{gg},$

\[\sum_{i=1}^{g-1} (b_i(\omega_1) a_i(\omega_2) - b_i(\omega_2) a_i(\omega_1)) + c(b_0(\omega_1) a_0(\omega_2) - b_0(\omega_2) a_0(\omega_1)) = 0.\]
The special role played by the band going with $a_\sigma$ could as well be played by any other band, say $a_{\sigma-1}$, leading to a similar relation

$$\sum_{i=1}^{\sigma} \left( b_i(\omega_1) a_i(\omega_2) - b_i(\omega_2) a_i(\omega_1) \right) + c'(b_{\sigma-1}(\omega_1) a_{\sigma-1}(\omega_2) - b_{\sigma-1}(\omega_2) a_{\sigma-1}(\omega_1) = 0,$$

implying that $c' = c = 1$.

**Remark.** For the case of the Toda systems in the other classical groups and $G_2$, one constructs a correspondence in a similar fashion between the curves (I, 3.15, 3.16) occurring in these cases. The correspondence is given by

$$(t, \lambda_m(t)) \rightarrow \left\{ t, \sum_{1}^{\tau} \alpha_\pi \lambda_{t(\pi)}(t) \right\} \text{ over all permutations } \pi \text{ such that } \lambda_{t(\pi)} = \pm \lambda_m(t) \text{ for some } t,$$

and one observes that the correspondence commutes with the involutions $\sigma$ on both curves given by $(h, z) \rightarrow (h, -z)$. Now up to isogeny, the involutions $\tau$ on $X, X'$ lead to the decompositions

$$\text{Jac } X = x + y, \quad \text{Jac } X' = x' + y',$$

where $y$ and $y'$ are the Prym varieties associated with $\sigma$, etc. The correspondence $C$ induces the complex multiplication (see the Appendix), where, for the sake of notation, we have identified $\text{Jac } X$ and the Riemann matrix of $X$:

$$\text{Jac } X' \cdot N = A \cdot \text{Jac } X,$$

i.e.,

$$(x' \oplus y') \cdot N = A \cdot (x \oplus y). \quad (13)$$

Upon observing that, at the level of $\text{Jac } X$, $\sigma$ induces the map $(\tilde{x}, \tilde{y}) \rightarrow (\tilde{x}, -\tilde{y})$, etc., and also that $\sigma$ commutes with $C$, we find that acting upon (13) with $\sigma$ implies

$$(x' \oplus (-y')) \cdot N = A(x \oplus (-y)). \quad (14)$$

Thus upon adding and subtracting (13) and (14), we find

$$x' \cdot N = A \cdot x, \quad y' \cdot N = A \cdot y. \quad (15)$$

One proves in the same fashion as in Lemma 1 that $C$ is singular, and hence the complex multiplications (15) are nontrivial; thus, $x', x$ and $y', y$, respectively,
have common abelian subvarieties, by Weil [22]. Thus the extra symmetry in these cases is reflected in the double factorization statement consistent with the symmetries of the Jacobians. We have that the linearizing Prym subvariety of $\text{Jac}(X)$ is contained in all the Pryms coming from all the different representations. Thus Theorem 1 has this strengthened form for these cases. Similar remarks can be made for the other examples in I, Section 4.

Appendix

The purpose of this appendix is to provide definitions and notations to Section 4 and to provide a clear but limited exposition of the classical theory of correspondences leading up to Theorem 4.1; the theory of correspondences was developed mainly by the Italian geometers. These results can be found in Coolidge's book [5] in an obscure way or can be proved using Chern classes of line bundles and modern intersection theory. Therefore we give an exposition in the spirit of this paper.

A correspondence $C[n, n']$ between two curves $X$ and $X'$ of genera $g$ and $g'$, respectively, is defined by one or several algebraic relations between the coordinates of $X$ and $X'$ mapping a point $p \in X$ onto $n'$ points $C(p) = \sum_{i=1}^{n'} q_i \in X'$ and a point $q \in X'$ onto $n$ points $C^{-1}(q) = \sum_{i=1}^{n} p_i \in X$.

Remark. Let $f(x, y) = 0$ and $f'(x', y') = 0$ define the curves $X$ and $X'$, respectively. Thus the correspondence $C[n, n']$ will be given by

$$\phi_1(x, y, x', y') = \phi_2(x, y, x', y') = \cdots = \phi_n(x, y, x', y') = 0.$$ 

In fact we show that these equations $\phi_i = 0$ ($1 \leq i \leq m$) can be replaced by at most two new algebraic equations: Given a point $(x', y') \in X'$, the intersection of the curves $f = 0$, $\phi_1 = 0$, ..., and $\phi_m = 0$ is given by $n$ points $(x_i, y_i)$ ($1 \leq i \leq n$), whose abscissae can be assumed generically distinct after possibly a birational transformation of coordinates. Let $y_j(x)$ be the solutions of the polynomial $f(x, y) = 0$ in $y$. Form the polynomial in $x$, $x'$, $y'$

$$\theta_i(x, x', y') = \prod_j \phi_i(x, y_j(x), x', y')$$

and let $\theta(x, x', y')$ be the polynomial\footnote{By the Euclidean algorithm for forming the g.c.d. this still is a polynomial.} in $x$, $x'$, $y'$ which is the g.c.d. of the $\theta_i$'s. The solutions in $x$ of this polynomial are precisely the points $x_i$, by the g.c.d. construction. Let $A(x)$ be the unique polynomial of degree $n$ in $x$, also depending on $x'$ and $y'$ such that $y_i - A(x_i) (1 \leq i \leq n)$; then the $n$ common solution of

$$\theta(x, x', y') = 0; \quad y - A(x) = 0, \quad A(x)$$

depending on $x'$ and $y'$,
provides us precisely with the \( n \) points \( x_i, y_i \). Moreover \( A(x) \) depends \textit{rationally} on \( x' \) and \( y' \), because \( A(x) \) is a symmetric function of the \( x_i \), which themselves are roots of the polynomial \( \theta(x, x', y') \) in \( x, x' \) and \( y' \); this uses the customary interpolation formula in the construction of \( A(x) \). Possibly undoing the preparatory birational transformation we have shown that a correspondence is defined by at most two equations \( \phi_i \) \((1 \leq i \leq 2)\). A dimension count shows that if two equations are fully needed, this would be rare indeed and, in fact, implies that the two curves \( X \) and \( X' \) are intimately related.

A \textit{singular} correspondence is one where \textit{two equations} are needed, i.e., one equation does not suffice.

We now show, following Hurwicz, how a correspondence implies a relation between the period matrices, as explained next. Let \( \omega_i \) \((1 \leq i \leq g)\) and \( \omega'_i \) \((1 \leq i \leq g')\) be the respective bases for holomorphic differentials on \( X \) and \( X' \). Then

\[
\sum_{j=1}^{n'} \omega'_i(q_j(p))
\]

is a holomorphic differential on \( X \), since upon integration it does not blow up and hence we have equality of the differentials

\[
\sum_{j=1}^{n'} \omega'_i(q_j(p)) = \sum_{k=1}^{g} a_{ik} \omega_k(p), \quad 1 \leq i \leq g', \tag{1}
\]

for some appropriate choice of \( a_{ik} \). Let \( c_i \) and \( c'_i \) be a basis of homology cycles on \( X \) and \( X' \), respectively. Then whenever \( p \) sweeps out a cycle \( c_i \), then \( C(p) = \sum q_j(p) \) sweeps out a cycle on \( X' \) of the form \( \sum_{m=1}^{b'_i} n_m c'_m \) with \( n_m \in \mathbb{Z} \). Hence upon integrating (1), we find our statement of complex multiplication, namely,

\[
\sum_{m=1}^{2g'} n_m c'_m(\omega_i) = \sum_{k=1}^{g} a_{ik} c_1(\omega_k), \quad 1 \leq l \leq 2g, 1 \leq i \leq g', \tag{2}
\]

or, equivalently,

\[
\Omega' N = A \Omega \quad \text{with} \quad (\Omega')_{ij} - c'_i(\omega_i) \quad \text{and} \quad \Omega_{ij} - c_j(\omega_i).
\]

In view of Riemann's bilinear relation \( \Omega J \Omega^T = 0 \), the latter implies

\[
\Omega' C \Omega^T = 0, \quad \text{where} \quad C = NJ \quad \text{is an integral matrix.}
\]

So a self-correspondence of \( X \) (i.e., a correspondence of \( X \) to itself) implies a quadratic integer relation between the elements of the period matrix

\[
\Omega C \Omega^T = 0 \quad \text{with} \quad C \quad \text{a} \; 2g \times 2g \quad \text{integral matrix.}
\]
Whenever this relation is different from Riemann's bilinear relation, it is called complex multiplication.

Given a correspondence $C$ of $X$ onto $X'$ define the numbers of coincidences:

$$\eta = \# \{p \in X \mid q_i = q_j \text{ for some } i \neq j\}$$

and

$$\eta' = \# \{q \in X' \mid p_i = p_j \text{ for some } i \neq j\}.$$ 

A self-correspondence of $X$ is said to have value $\gamma$ if for any two points $p, q \in X$

$$C(p) + \gamma p = C(q) + \gamma q \quad \text{in Jac}(X).$$

Let $\xi$ be the number of fixed points (i.e., such that $\xi \in C(\xi)$). The Chasles-Cayley-Brill formula (Coolidge [5, p. 129, Theorem 14]) affirms that for any self-correspondence $C[n, n']$ of $X$,

$$\xi = n + n' + 2\gamma n.$$ 

Let $f_0, ..., f_r$ be $r + 1$ independent meromorphic functions. Then the $r$-dimensional family of zero divisors of the functions

$$f = \lambda_0 f_0 + \lambda_1 f_1 + \cdots + \lambda_r f_r$$

with $\lambda_k \in \mathbb{C}$ defines a linear system $g_{N^r}$, where $N$ is the order of the minimal divisor $\mathcal{D}$ of poles of the $f_i$'s. Then given $r$ generic points $p_1, ..., p_r$ on $X$ and since for this generic choice $\det(f_i(p_j)) \neq 0$, $1 \leq i, j \leq r$, unique constants $\lambda_1, ..., \lambda_r$, up to a factor, can be found such that for $1 \leq j \leq r$, and for a fired $\lambda_0$,

$$\lambda_0 f_0(p_j) + \sum_{i=1}^{r} \lambda_i f_i(p_j) = 0,$$ 

defining $N - r$ other zeros. In particular a linear system $g_{N^1}$ associated with $\lambda_0 f_0 + \lambda_1 f_1$ defines a self-correspondence $C[N - 1, N - 1]$ of $X$ ($f(x, y) = 0$) by the $N - 1$ nontrivial solutions of

$$F_1 = \frac{f_1(x, y) f_0(x', y') - f_0(x, y) f_1(x', y')}{x' - x} = 0.$$ 

Clearly this self-correspondence has value $\gamma = 1$ because for any choice of $p$ and $q$,

$$(\lambda_0 f_0 + \lambda_1 f_1) = p + C(p) - \mathcal{D} \quad \text{for} \quad \lambda_0/\lambda_1 = -f_1(p)/f_0(p).$$

\[23\] Counted with multiplicities.
and
\[(\lambda'_0 f_0 + \lambda'_1 f_1) = q + C(q) - D \quad \text{for} \quad \lambda'_0/\lambda'_1 = -f_1(q)/f_0(q).\]
Therefore
\[(\lambda' f_0 + \lambda'_1 f_1) = p + C(p) - q - C(q) \equiv 0 \quad \text{in} \quad \text{Jac} \ X,
\]
which implies that \( \gamma = 1. \) From the Chasles–Cayley–Brill formula applied to \( C[N-1, N-1], \) it follows that
\[d = 2 \# \{\text{divisors in } g_N \text{ with double points}\}
= (N - 1) + (N - 1) + 2g = 2(N - 1 + g).
\]
An algebraic system \( \gamma_N \) of index \( v \) on a curve \( X \) is defined by a curve \( X' \) and a correspondence \( C[N, v] \) between \( X \) and \( X'; \) so, the algebraic system \( \gamma_N \) is given by the family of common zero divisors of order \( N \) of
\[w, y, x', y' = 0 \quad \text{in} \quad (x, y) \in X\]
parametrized by \( (x', y') \in X'. \) Moreover any point \( (x, y) \in X \) corresponds to the \( v \) zero-divisor corresponding to the \( v \) roots \( (x', y') \) of \( \phi_2 = 0 \) on \( X'. \)

Let \( d \) have the same meaning as above but for \( g_N \) replaced by \( g_{N-1}; \) unfortunately this number cannot be computed in the above fashion; one would be tempted to replace the above formula for \( d \) by \( 2v(N - 1 + g); \) however, this only produces an upper bound (Lemma 4). The above recipe for providing the correspondence does not generalize to \( \gamma_N \).

**Lemma 1.** A deformable algebraic system \( \gamma_N \) of index 1 on \( X \) is a \( g_N \).

**Proof.** Consider the self-correspondence of \( X \) defined by
\[C(p) = \text{the divisor of } N \text{ points of } \gamma_N \text{ containing } p.\]
Consider now a one-parameter \( (\beta) \) family of \( \gamma_N \)'s and the corresponding \( C^\beta; \) let \( C^0 = C. \) Then the numbers \( a_{ik} \) in (1) do not depend on the parameter in view of (2). Indeed let \( \omega_1, \ldots, \omega_g \) be a normalized basis such that \( c_l(\omega_k) = \delta_{lk} \) \((1 \leq l, k \leq g)\). Then from (2) with \( g = g' \)
\[a_{ik} = n_{ik} + \sum_{m=g+1}^{2g} n_{mk} c_m(\omega_i), \quad 1 \leq i, k \leq g,
\]
and any continuous variation of the parameter \( \beta \) above leaves the integers \( n_{ij} \) and the periods \( c_m(\omega_i) \) fixed. Hence \( a_{ik} \) is constant with \( \beta. \)
Moreover for any \( p' \in C^\beta(p), p' \neq p \), we have that \( C^\beta(p') = C^\beta(p) \); so, upon integration of (1) from \( p_0 \) to \( p \), we have

\[
\sum_{k=1}^{g} a_{ik} \int_{p_0}^{p} \omega_k = \int_{N_{p_0}}^{C^\beta(p)} \omega_i + d_i^\beta = \int_{N_{p_0}}^{C^\beta(p')} \omega_i + d_i^\beta
\]

\[
= \sum_{k=1}^{g} a_{ik} \int_{p_0}^{p'} \omega_k \quad \text{in Jac}(X), \quad p' \in C^\beta(p),
\]

where \( d_i^\beta \) is an integration constant independent of \( p \). Now we pick a pair of points \( p_1, p_2 \), which shall be fixed throughout the following argument. We can find a deformation \( C^\beta \) of \( C^0 = C \) such that for \( \beta = \beta_0, \ C^\beta(p_1) = C^\beta(p_2) \), and hence in (3), setting \( p = p_1, p' = p_2, \beta = \beta_0 \), we have

\[
\int_{N_{p_0}}^{C^\beta(p_1)} \omega_i + d_i^{\beta_0} = \sum_{k=1}^{g} a_{ik} \int_{p_0}^{p_1} \omega_k
\]

\[
= \sum_{k=1}^{g} a_{ik} \int_{p_0}^{p_2} \omega_k = \int_{N_{p_0}}^{C^\beta(p_2)} \omega_i + d_i^{\beta_0} \quad \text{in Jac}(X).
\]

Since a variation in \( \beta \) leaves the \( a_{ik} \) unaltered, the two middle expressions are in fact also unaltered, and so the extreme expressions in (4) are also independent of \( \beta \), and equal; therefore putting \( \beta = 0 \) we conclude

\[
\int_{N_{p_0}}^{C(p_1)} \omega_i = \int_{N_{p_0}}^{C(p_2)} \omega_i \quad \text{on Jac}(X),
\]

and therefore

\[
C(p_1) = C(p_2) \quad \text{in Jac} X, \quad \text{for all} \ p_1, p_2 \in X.
\]

Hence by Abel’s theorem, we have a rational function on \( X \), algebraic in \( \lambda \)

\[
g(p, \lambda) \quad \text{such that} \quad (g) = D_\lambda - D, \ D_\lambda, D \in \gamma_{N,1},
\]

\( \lambda \) being the parameter in \( \gamma_{N,1} \). Since the index of \( \gamma_{N,1} \) is one, \( g \) can be taken rational in \( \lambda \), also; given \( p \in X \), there is precisely one solution to \( g(p, \lambda) = 0 \), and so \( g \) is linear in \( \lambda \), thus \( \gamma_{N,1} \) is a \( \gamma_{N,1} \).

**Corollary 1.** Given a deformable \( \gamma_{N,1} \) of index \( \nu \), the divisors \( (C^{-1} \circ C)(p) \) (i.e., sum of the groups containing \( p \)) parametrized by \( p \in X \) form a \( \gamma_{N,1} \) of index 1 and hence by Lemma 1, a linear system \( g_{N,1}^1 \).
LEMMA 2 (Zeuthen's formula). The following relation holds:
\[ \eta + 2n'(g - 1) = \eta' + 2n(g' - 1). \]

Proof. First, assume \( n = 1 \) and let \( X \) be an \( N \)-fold covering of \( C \). Then according to the Riemann–Hurwitz formula for the ramification indices \( V_X \) and \( V_{X'} \) of \( X \) and \( X' \),

\[ V_X = 2(N + g - 1) \quad \text{and} \quad V_{X'} = 2(Nn' + g' - 1). \]

But observing that among the branch points of \( X' \), some of them come from \( X \) by the correspondence and the others come from the coincidences, we have

\[ V_{X'} = n'V_X + \eta. \]

Comparing these three formulas yields

\[ \eta = 2(g' - 1) - 2n'(g - 1). \quad (5) \]

Second, for arbitrary \( n \), there is a natural correspondence \( C^w[1, n'] \) from \( X \) to the graph curve \( \Gamma' \) (associated with the correspondence \( C[n, n'] \)) with genus \( g'' \); it maps \( p \in X \) onto \( n' \) points \((p, q_1), \ldots, (p, q_{n'}) \in \Gamma\). Similarly, there is a correspondence \( C^w[1, n] \) from \( X' \) to \( \Gamma \). Applying formula (5) to these two new correspondences and eliminating \( g'' \) from them leads to the desired result.

LEMMA 3 (Severi's formula). For a given curve \( X \) of genus \( g \), and \( r \geq 1 \), a linear system \( g_N \) and an algebraic system \( \gamma_M \) of index \( \nu \), having \( d \) coincidences

\[ \# \{ p = p_1 + \cdots + p_{r+1} \text{ such that } p + \cdots \in g_N \text{ and } p + \cdots \in \gamma_M \} \]

\[ = 2N \binom{M - 1}{r} \nu - \frac{1}{2} d \binom{M - 2}{r - 1}. \]

Proof. Let \( \phi(N, r, M) \) be this number for \( r \geq 0 \). Consider the correspondence of \( X \) onto itself mapping a point \( p \) onto a divisor \( C(p) \) to be constructed as follows:

(i) To \( p \in X \), associate the \( \nu \) sets of points \( q_1^i + \cdots + q_{M_i}^i \) (\( 1 \leq j \leq \nu \)) such that

\[ p + q_1^i + \cdots + q_{M_i}^i = p + Q(p) \in \gamma_M. \]

(ii) Take any one of the \( \binom{M - 1}{r} \) distinct divisors \( Q^i = q_{i_1}^1 + \cdots + q_{i_r}^1 \) for \( I = (i_1, \ldots, i_r) \) among the set \( Q(p) \) not containing \( p \); then to each such divisor there corresponds a unique one \( P_{i_1} + \cdots + P_{i_r} \in g_N \) such that

\[ Q^i + P_i \in g_N. \]
This defines a correspondence:\footnote{We do not exhibit the polynomials defining this correspondence.}

\[
C(p) = \sum_{\rho \in C'_{[2, M]}_r} P^j + \binom{M - 2}{r - 1} \sum_{j=1}^r Q^j(p)
\]

of type

\[
C = C \left[ (M - r) \phi(N - 1, r - 1, M) + \nu(M - 1) \binom{M - 2}{r - 1}, \nu(N - r) \binom{M - 1}{r} \right.
\]

\[
+ \nu(M - 1) \binom{M - 2}{r - 1}].
\]

We now explain the index count: the latter index can be read off from the divisor $C(p)$. Conversely, given a point $p' \in C(p)$; then $p'$ can appear either in the first or the second sum in $C(p)$. In the latter case, there are $\nu$ ways to add $(M - 1)$ points to $p'$ to make a divisor in $\gamma^1_M$, and thus multiplying $\nu(M - 1)$ with $\binom{M - 2}{r - 1}$, the multiplicity with which the $p'$ appears, we get the latter contribution to the first index of $C$. The other contribution is obtained by taking $p' \in \sum P^j_i$. Note that the divisors of $g^r_N$ containing $p'$ form a $g^r_{N-1}$, and if we look at the $\mathfrak{D} \in g^r_{N-1}$ having $r$ points in $\gamma^1_M$, of which there are $\phi(N - 1, r - 1, M)$, then the remaining $(M - r)$ points of the $\gamma^1_M$ are precisely the candidates for $p$. This explains the indices of $C$. The next point to observe is that the value $\gamma$ of $C$ is zero; indeed, since the combinatorial identity $\binom{M - 2}{r - 1} \sum Q^j(p) = \sum Q^j_i$, implies

\[
C(p) = \sum (P^j_i + Q^j_i),
\]

and since the $P^j_i + Q^j_i(p) \in g^r_N$ are independent of $p$ in $\text{Jac}(X)$, we have that $\gamma = 0$. Hence by the Chasles-Cayley-Brill formula $\xi = n + n' + 2\gamma$,

\[
\xi = (M - r) \phi(N - 1, r - 1, M) + \nu(M - 1) \binom{M - 2}{r - 1} + \nu(N - r) \binom{M - 1}{r} + \nu(M - 1) \binom{M - 2}{r - 1}.
\]

The coincidences $\xi$ can also be counted directly. We will have a coincidence whenever $p$ coincides with $\sum Q^j_i(p)$ or $\sum P^j_i$. The first case occurs $d \times \binom{M - 2}{r - 1}$ times, where $d$ is the coincidence of the $\gamma^1_M$. The second case occurs precisely if $p \in P^j_i$ for some $j, I$, but that happens precisely if the $r + 1$ points $Q^j_i(p) + p$ are common to $\gamma^1_M$, $g^r_N$, i.e., $\phi(N, r, M)$ times, and of course all of the $r + 1$ elements of $Q^j_i(p) + p$ give rise to such an occurrence, which thus occurs $(r + 1) \phi(N, r, M)$ times. We thus conclude

\[
\xi = \binom{M - 2}{r - 1} d + (r + 1) \phi(N, r, M).
\]
Upon equating the above expressions for $\xi$ we have the recurrence relation

$$(M - r)\phi(N - 1, r - 1, M) + \nu(M - 1) \binom{M - 2}{r - 1} + \nu(N - r) \binom{M - 1}{r}$$

$$+ \nu(M - 1) \binom{M - 2}{r - 1} = \binom{M - 2}{r - 1} d + (r + 1) \phi(N, r, M).$$

(6)

We now proceed by induction. Suppose $\phi(N, s, M)$, $s < r$ has the desired form for all $N$; then a straightforward combinatorial computation shows that $\phi(N, r, M)$ also does, by substitution. To start the induction put $r = 1$ in (6) using $\phi(N - 1, 0, M) = \nu(N - 1)$, leading to the correct expression for $\phi(N, 1, M)$. This proves Lemma 3.

**Lemma 4.** The coincidences of a correspondence $C[n, n']$ between $X$ and $X'$ satisfy

$$\eta' \leq 2n'(n + g - 1)$$

and

$$\eta \leq 2n(n' + g' - 1).$$

**Proof.** A correspondence $C[n, n']$ gives rise to a $\gamma_{n'}^1$ of index $n'$. Observe that

$$d = 2 \# \{\text{divisors of order } n \text{ in } \gamma_{n'}^1 \text{ with double points} \} = 2\eta'.$$

According to Lemma 3 and because of the nonnegativity of $z$, $z = \# \{ p = p_1 + \cdots + p_n \in \gamma_{n'}^1 \text{ such that } p + \cdots \in \gamma_{n' + g - 1}^1 \} = 2n'(n + g - 1) - \eta' \geq 0$, from which Lemma 4 follows.

**Theorem 1.** (Castelnuovo) The following four statements are equivalent:

(i) $x = 0$

(ii) $\gamma_{n'}^1$ is contained in a linear series $g_{n'}^1$

(iii) the correspondence of $\gamma_{n'}^1$ is given by one equation,

(iv) the homomorphism between $\text{Jac}(X)$ and $\text{Jac}(X')$ induced by the correspondence is trivial.

**Proof.** (i) implies (ii). To begin with, let $x \geq 0$ be arbitrary; let $\gamma_{n'}^1$ be given by the equations

$$f(x, y) = F_1(x, y, x', y') = F_2(x, y, x', y') = f'(x', y') = 0.$$ 

Take a generic $g_{n' + g - 1}^1$ defined by

$$\psi = \sum_{i=1}^{n} \lambda_i \psi_i = 0.$$
Eliminate $y$ from $f$ and $F$; this yields a polynomial

$$\theta_1(x, x', y') = 0.$$  

Eliminate $y$ from $f$ and $F$:

$$\theta_2(x, x', y') = 0.$$  

Given a point $(x', y')$ on $X'$, there are $n$ solutions $(x_1(x', y'),..., x_n(x', y'))$ to these two equations (possibly after a birational transformation), i.e., $n$ points on $X$. Eliminating $y$ between the equation $\psi$ and $f$ yields a polynomial

$$\Theta(x, \lambda_1, \lambda_2,..., \lambda_n) = 0.$$  

Now we express the fact that the $n$ roots $x_i(x', y')$ are also roots of $\Theta = 0$. This yields

$$\Theta(x_i(x', y'), \lambda_1,..., \lambda_n) = 0, \quad 1 \leq i \leq n, \text{ where } f'(x', y') = 0.$$  

Note that this equation is parametrized by the $g_{n+g-1}^{n-1}$'s. Assume now $z = 0$, i.e., there is generically (in $g_{n+g-1}^{n-1}$) no solution to this system of equations in $\lambda_1,..., \lambda_n$ for all $(x', y')$ with $f(x', y') = 0$. But now we exhibit a special $g_{n+g-1}^{n-1}$ for which there is a solution; then for the $\psi$ corresponding to the special choice of $g_{n+g-1}^{n-1}$ there are an infinite number of solutions, by Bezout's theorem. To get a special $\psi$, take a group $a$ of $\gamma_{n-1}$ and $g$ other points $p_1,..., p_g$ such that

$$a = \sum_{1}^{g} p_i \in g_{n+g}^{n}.$$  

Pick $p_1$. Let $\tilde{g}_{n+g-1}^{n-1}$ be the fixed linear system\(^\text{25}\) such that

$$\tilde{g}_{n+g-1}^{n-1} + p_1 \subseteq g_{n+g}^{n}.$$  

But since

$$a + p_1 + \cdots \in g_{n+g}^{n},$$  

we have that

$$a \in \tilde{g}_{n+g-1}^{n-1}.$$  

\(^25\) Fixing one point in a linear system leads to a linear system of one fewer points and one fewer degrees of freedom. Indeed given a system defined by $\sum_{0}^{n} \lambda_i f_i(p) = g(\lambda, p) = 0$ and imposing the condition $g(\lambda, \tilde{p}) = 0$ enables us to eliminate, say, $\lambda_0 = -(f_0(\tilde{p}))^{-1} \sum_{i=1}^{n} \lambda_i f_i(\tilde{p})$, and thus substituting in the above yields a linear system of the form $\sum_{i=1}^{n} \lambda_i h_i = 0$. 

and since \( a \in \gamma_n^1 \) we have indeed exhibited the right \( \bar{g}_{n+g-1}^{n-1} \) and thus
\[
\gamma_n^1 + \cdots \subseteq \bar{g}_{n+g-1}^{n-1}
\]
and therefore
\[
(\gamma_n^1 + p_1) + \cdots \subseteq \bar{g}_{n+g-1}^{n-1} + p_1 \subseteq g_{n+g}^n.
\]
Hence by symmetry
\[
(\gamma_n^1 + p_i) + \cdots \subseteq g_{n+g}^n, \quad 1 \leq i \leq g.
\]
(7)

Let \( b \in \gamma_n^1 \); then for some unique divisor \( c = c(b) \)
\[
b + c \in g_{n+g}^n.
\]
But, by (7), \( p_i \in c \); we conclude \( c = \sum_{i=1}^{g} p_i \). Hence
\[
\gamma_n^1 + \sum_{i=1}^{g} p_i \subseteq g_{n+g}^n.
\]
Therefore \( \gamma_n^1 \) is contained in a linear system \( g_{n+g}^{1+k}, \ k \geq 0 \). To establish the converse \((ii) \Rightarrow (i)\), assume \( \gamma_n^1 \subseteq g_{n+g}^{1+k} \), which is complete; we need to show that \( \gamma_n^1 \) and an arbitrary (complete) \( g_{n+g-1}^{n-1} \) have nothing in common. Now, assume to the contrary, that \( z > 0 \); let \( a \) be that divisor, i.e., for some points \( p_1, \ldots, p_{g-1} \).
\[
a + \sum_{i=1}^{g-1} p_i \in g_{n+g-1}^{n-1}, \quad a \in \gamma_n^1.
\]
Fixing \( \sum_{i=1}^{g-1} p_i \) determines a unique complete \( \bar{g}_n^h \) such that
\[
\bar{g}_n^h + \sum_{i=1}^{g-1} p_i \subseteq g_{n+g-1}^{n-1}
\]
which clearly also contains \( a \); therefore
\[
a \in \bar{g}_n^h \cap g_{n+g-1}^{1+k}
\]
and hence they coincide; thus
\[
\gamma_n^1 \subseteq g_{n+g-1}^{1+k} = \bar{g}_n^h \subseteq g_{n+g-1}^{n-1}.
\]

\textsuperscript{25} See footnote 25.

\textsuperscript{26} Because the divisors of both linear systems are equivalent to \( a \) in \( \text{Jac}(X) \) and both systems are complete by assumption.
which is absurd, because every generic linear system $g_{n+1}^{n-1}$ would have something in common.

We now show that (ii) implies (iii); so assume $\gamma_n \subseteq g_{n}^{l}$. Embed the curves $X$ and $X'$ in projective spaces $(\mathbb{P}^l)^*$ and $\mathbb{P}^l$, $l \geq 2$, respectively, as follows: if $\psi = (\psi_0, \ldots, \psi_l)$ are the defining meromorphic functions for $g_{n}^{l}$, define the map

$$p \in X \rightarrow \psi(p) \in (\mathbb{P}^l)^*$$

and a hyperplane $\{x | (y, x) = \sum_{i=1}^{l} y_i x_i = 0\}$ intersects $X$ in the points $\psi(p_1), \ldots, \psi(p_n)$, where $(y, \psi(p_j)) = 0$ ($1 \leq j \leq n$); therefore we can identify the hyperplane with a divisor in $g_{n}^{l}$. Also note that $y$ may be thought of as an element of $\mathbb{P}^l$. Let $C: X \rightarrow X'$ be the correspondence associated with $\gamma_n^1$; if $p' \in X'$, then $C^{-1}(p') \in g_{n}^{l} \simeq \mathbb{P}^l$; therefore $X'$ can be embedded in $\mathbb{P}^l$. Let $X$ and $X'$ be given by

$$X: f(x) = 0, \quad X': f'(x') = 0.$$ 

Then the correspondence is given by

$$\sum_{i=0}^{l} x_i y_i = 0,$$

which produces the one equation defining the correspondence, establishing (iii).

Now assume (iii): the correspondence is given by one equation, besides the curve equations

$$f(x, y) = 0, \quad f'(x', y') = 0, \quad R(x, y, x', y') = \sum_{i,j} \lambda_{ij}(x', y') = 0,$$

where $\lambda_{ij}$ are also polynomials in $(x', y')$. Note that for different values of $(x', y')$ the divisors of zeros of $R$ are equivalent in $\text{Jac}(X)$. This implies that the map defined by

$$p' \in X', \quad f(p') = \int_{C(p')}^{\omega} \omega \in \text{Jac}(X),$$

is constant. Think of $X'$ as being embedded in $\text{Jac}(X')$; then any map $f$, as defined above, extends by linearity to a unique homomorphism

$$h: \text{Jac}(X') \rightarrow \text{Jac}(X) \quad \text{with} \quad h |_{X'} = f,$$

possibly after a new choice of origin. The fact that $f = \text{constant}$ implies that $h \equiv 0$ on $\text{Jac}(X)$, establishing (iv). That (iv) implies (iii) can be done by retracing one's steps. This ends the proof of Theorem 1.
LINEARIZATION OF SYSTEMS
